1.0 SUMMARY

In 1976, Orbit Gas Company, Owensboro, Kentucky, drilled a well located in the East Crofton Field of Christian County, Kentucky. The well was drilled to a depth of 2592 ft.

A four inch diameter oriented Devonian Shale core was obtained from 2178 ft. to 2327 ft. Of the original 149 ft. of core, 128 ft. was recovered. Battelle Research Laboratories and Mound Facility received samples of the core for analysis. Schlumberger Well Services ran the following suite of logs: Spontaneous Potential, Simultaneous Compensated Neutron - Formation Density, Microlaterolog - Microlog, Bore Hole Compensated Sonic Log, and a dual Induction-Laterolog. Following the logging of the hole the casing was set at 2360 ft.

The interval between 2186 ft. and 2320 ft. (134 ft.) was selected for stimulation with foam. The zone was shot with ten, 0.48" holes and broken down with acid. No measurable gas was observed during the swabbing operation or after the acid treatment.

On November 4, 1976, foam frac of the New Albany Shale was performed by Halliburton Services with the assistance of Aircowell's Nitrogen Gas Service A total of 45,000 gallons of 78 quality foam carrying 54,000 lbs. of frac sand was used in the treatment. Formation breakdown pressure was 1,800 psi and the average injection rate of the frac fluid was 5.6 barrels per minute.

The final open flow of gas from the well, after the foam treatment, was established at 2 MCF per day. Well head pressure build-up after a 115 day shut-in period was 836.6 psig.

After consultation with DOE personnel, it was decided to restimulate the black shale. The interval between 2187 to 2331 ft. was shot with 280 quarts of oil well explosive (Nitro). One hour after the shot, flow from the well was gauged at 40 MCF per day. The well's final open flow was calculated to be approximately 15 MCF per day.

The well has been plugged and abandoned because of non-commercial gas production.

2.0 WELL SITING

Orbit Gas well, Ray Clark #1, is located in Christian County, Kentucky (Figure 2.1). The approximate co-ordinates of the well are 87° 25' 5" and 37° 2' 3". The drill site is located 607 ft. south of the Kentucky highway 800, 90 ft. from the east line and 650 ft. from the north line of Carter Section 12 (Figure 2.3). The selection of the site was based on the following criteria:

- Favorable Geologic setting.
- Proximity to known Devonian shale products.
- Proximity to pipeline for marketing of the gas.
- Favorable leasing position for the contractor in this test area.

The well is located along the south side of the Massive Pennyrile Fault system of Western Kentucky (see Figures 2.2 and 2.3). This location is considered favorable because of the structure and natural fracturing associated with faulting in the area. The structure on the base of the Vienna Limestone, which outcrops in the area is outlined in the map (Figure 2.2).

In western Kengucky, the New Albany Formation (the name of the Devonian Black shale in the Illinois Basin) of Upper Devonian age is sequentially overlain by the New Providence shale and the Fort Payne Formation both of the lower Mississippian age. The systemic boundary is placed at the contact between the New Providence shale and the New Albany Formation. A thin interval of limestone, the Rockford Limestone, occurs at the base of the New Providence shale i.e., immediately overlying the New Albany shale.

Within the test area one well (King Badget #1) was previously drilled. Devonian shale was encountered between 2,091 ft. to 2,273 ft., or a thickness of 182 ft. The temperature log indicated that the bottom 75 ft. of this section was gas-bearing. No measurable open flow was indicated. The well was treated with explosive stimulation and gas flow after stabilization was measured at 71 MCF/D.

3.0 DRILLING/CORING, LOGGING, CASING AND CEMENTING OPERATIONS

Drilling and Coring Operations

On September 8, 1976, Cresent Drilling Company started the drilling operations of well Ray Clark #1 for Orbit Gas Co. Twenty-five ft. of surface hole was drilled and cased with an 8 5/8-inch surface casing. The surface casing was set with the bottom of the casing located at the base of the Vienna lime. Fluid circulation was lost while drilling the rat hole and cement was spotted at the same time the surface casing was set. Fifty sacks of cement and 100 pounds of calcium chloride was used for both jobs. The cementing operations were performed by General Oil Well Cementing Company of Owensboro, Kentucky.

After waiting on cement, Cresent commenced drilling out under the surface casing on September 10, 1976. At 952 ft. a drill stem test was run. After the drill stem test was completed, drilling continued steadily until September 12, 1976 when the core point of 2,178 ft. was reached. The core point was determined by an examination of drill cuttings.

The nominal diameter of the hole upon reaching core point was 7 7/8 in. Since the outside diameter of the core bit was 7 27/32 in., it was assumed that no reaming of the hole would be necessary prior to coring. The well was cored by Christiansen Diamond Tool Company. A total of 149 ft. of 4-in. core between 2,178 ft. to 2327 ft. was extracted taking 88 hours of rig time. The core itself was inspected, measured and marked for identification, boxed and taken from the well site by representatives of the Illinois Geological Survey for further study and analysis. A representative of Battelle Research Laboratories collected sample sections, which were sealed for further laboratory tests. Results obtained from Battelle Research Laboratories, Illinois Geological Survey, and Mound Labs are given in Appendices B, C, D. Following the coring operation the drilling was resumed and the well drilled to a total depth of 2,592 ft.

Logging Operations

After reaching total depth, the driller circulated mud to clean up the hole for the logging operation. Logging, which was performed by

Schlumberger Well Services, commenced on September 22, 1976 and continued until September 23, 1976. The suite of logs run were as follows:

1. Gamma Ray
2. Formation Density Compensated
3. Caliper
4. Dual Induction- Laterolog
5. Micro Laterolog
6. Compensated Neutron
7. Sonic
8. Spontaneous Potential

Two logs, temperature and sibilation, which were planned but could not be run because the borehole was filled with drilling mud. All logs were taped for computer processing and a Coriband analysis was made. Copies of the logs at selected depths are included in Appendix F. The Kerogen Analysis for the Depth cored is presented in Appendix E.

Casing

Following the logging of the hole, a production string of 4½" O.D. J-55 casing was run and cemented in the hole with 875 sacks of 50-50 Pozmix cement and 18% salt. The casing was set at 2,360 ft. with a formation packer. Cementing was done by Halliburton, and the plug pumped to the bottom to leave the casing free of cement. A schematic well diagram is shown in Figure 3.1.

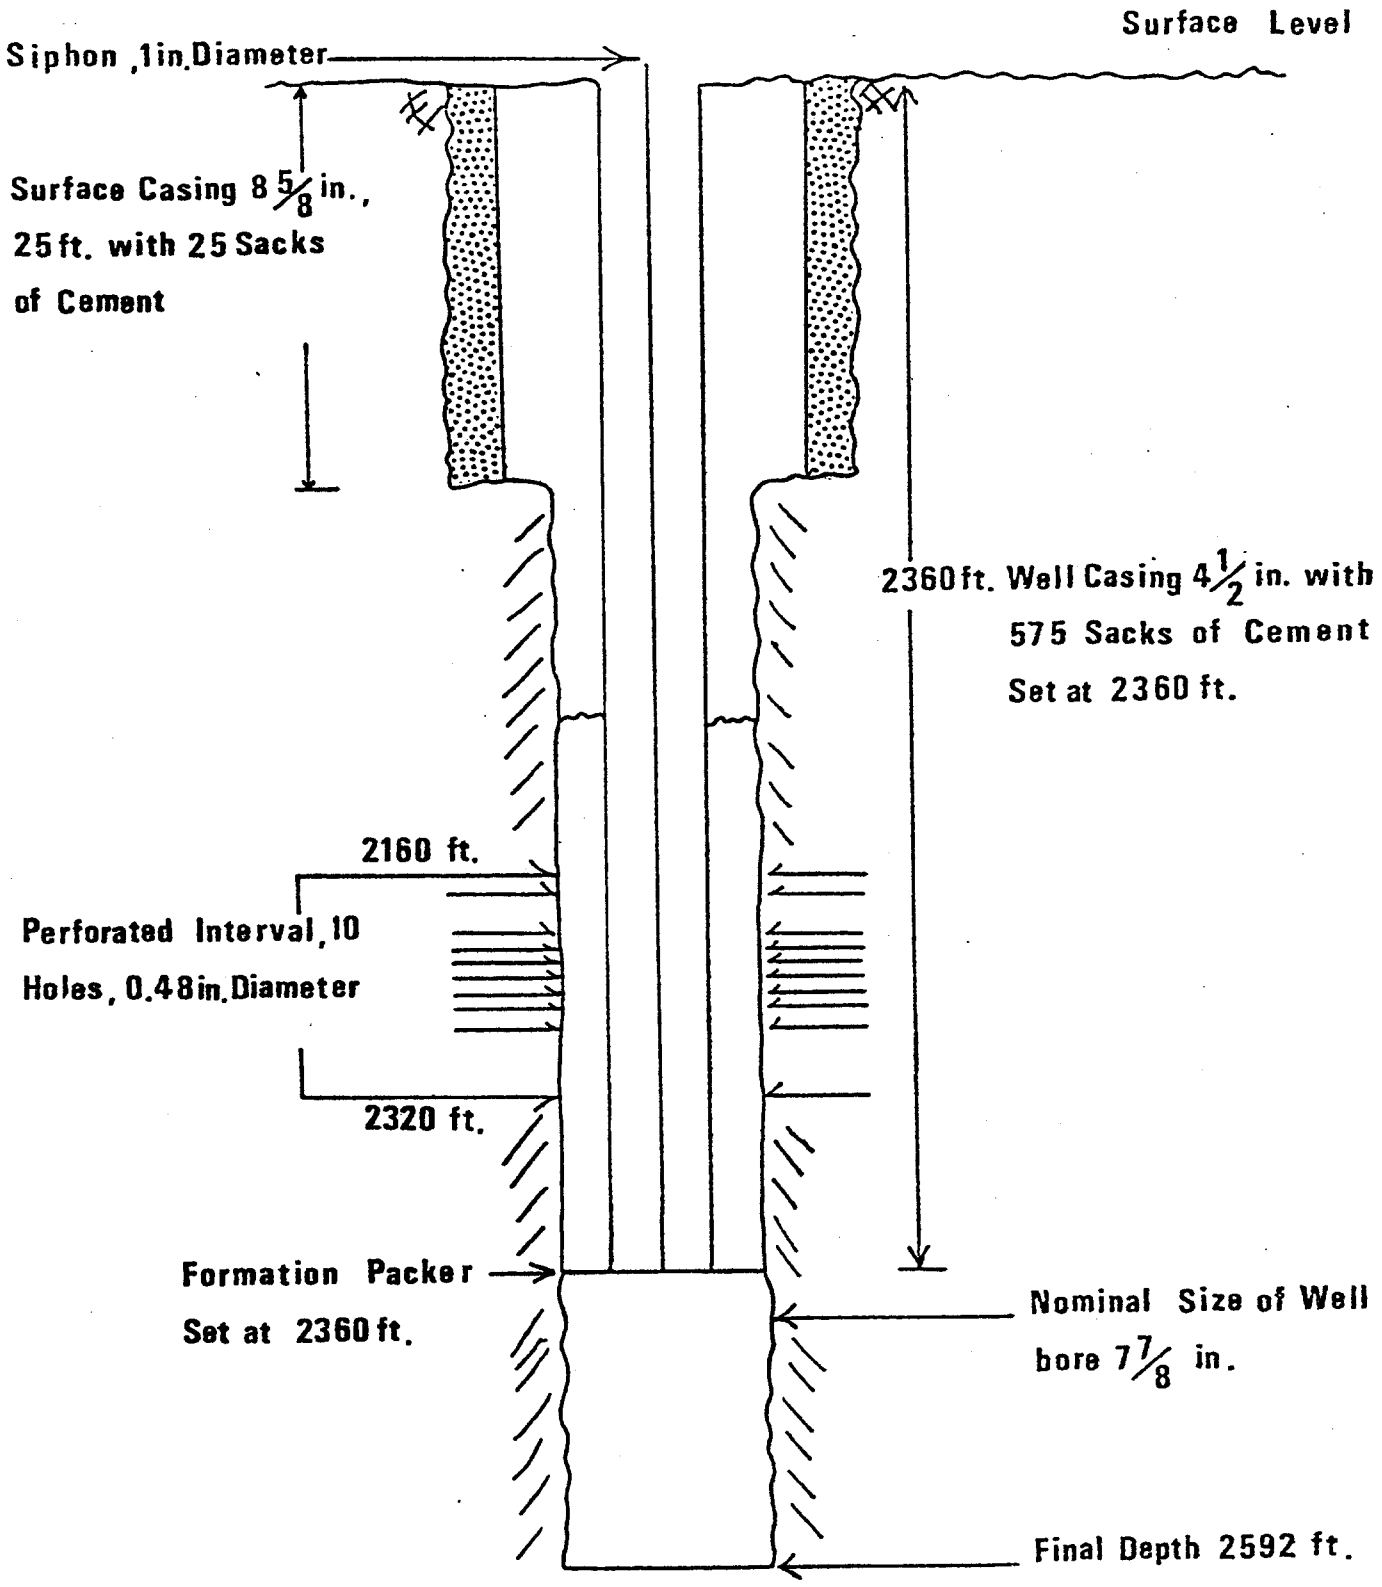

Figure 3.1 **Ray Clark Well # 1**

4.0 CORE DATA AND DESCRIPTION

Generalized Description of Core

The top of the New Albany Shale was encountered at 2175 ft.; the base, at 2321 ft. Thus, the thickness of the shale is 146 ft.

The New Albany Shale is predominantly brownish black, thickly laminated pyritic shale. Pyrite occurs as disseminated grains (probably replacing spore casings), in irregular concretionary masses, and as discrete laminae. Thin beds and laminae of dark colored silty shale and siltstone occur sparsely and irregularly throughout the section, commonly in groupings of two, three or more. Thin beds and laminae of light colored pyritic dolomite or sandy dolomite are more numerous, especially towards the base. Lithologic features of the New Albany Shale that appear to be restricted within the section are the following (from top to bottom):

(1) Phosphatic nodules: one observed within three feet of the top.

(2) Thin beds of olive gray shale: restricted to a 30 ft. interval in the middle of the formation.

(3) Calcareous (acid reactive) brownish black, thinly laminated shale containing scattered thin beds of light colored limestone and sandy limestone: basal 19 feet, (the contact between acid reactive shale and non-acid reactive shale is very sharp, though no color difference could be detected between the two types. This is a potentially significant observation that may have a bearing on gas production).

Natural fractures were strikingly absent from most of the core. Unfilled vertical fractures, however, were observed within an interval of 23 ft. between 43 ft. and 20 ft. above the base of the New Albany shale. These fractures were not numerous.

The entire New Albany Shale section was conspicuously lacking in hydrocarbon odor. The underlying Helderburg Limestone, however, exhibited a strong and very persistent hydrocarbon odor. Core samples were shipped to various organizations such as Battelle Research Laboratories, Illinois Geological Survey, and Mound Labs for analysis. The physical and chemical analysis determined by these contractors are given in Appendices B, C, and D. A summary of reservoir data generated through core analysis is presented in Table 4.1.

5.0 STIMULATION OPERATIONS

Perforation

The casing was swabbed and found to be clear of cement to a depth of 2,352 ft. This point was 28 ft. below the base of the New Albany Shale. A Gamma ray-Neutron log was then run in the empty hole to properly locate the perforations. The perforations were made in the open hole, with no fluid present, using a hollow steel carrier gun with 80 gram jet shots of 0.48 inch diameter with a rated penetration depth of 7.7 inches (Berea Sandstone Standard). The location of the perforations was one shot each at depths of 2,186', 2,198', 2,248', 2,270', 2,280', 2,290', 2,300', 2,310', 2,315', and 2,320'. The Gamma ray-Neutron log and perforation operations were performed by Birdwell. A slight amount of gas was noted in the well casing after the perforations were completed but the flow was insufficient to measure.

Acidization of Perforations Prior to Foam Frac

The acid treatment prior to foam fracturing consisted of pumping 500 gallons of 10% mud clean-out acid mixed with one gallong of inhibitor and three gallons of "cla-sta" into the well followed by 38 barrels of water. The job was performed on November 4, 1976. A breakdown pressure of 1,250 psig was required at the surface to start injection of acid, and a pumping time of 15 minutes was required for the injection. Average injection pressure was 900 psig. No gas was observed in the well bore during the swabbing operation after the acid treatment.

Foam-Frac of tne New Albany Shale

On November 5, 1976 the well was foam-fraced in the New Albany shale. The frac consisted of the high pressure injection of 45,000 gallons of 78 quality foam carrying a total of 54,000 pounds of frac sand with additives to reduce formation swelling. Two grades of sand were used. An initial 3,000 pounds of fine 100 mesh sand was used as a pre-pad to leak-off into natural fractures. This was immediately followed by 51,000 pounds of the coarser 20/40 mesh sand to provide the permeability required for flow of gas from the fractured formation. The foam used as a carrying

agent for the sand consisted of a total of 88 gallons of Halliburton's HC-2 detergent, 712,500 cubic feet of nitrogen and 300 barrels of water. Additives mixed with the injected foam and sand were 7 gallons of "cla-sta" and six sacks of calcium chloride. Surface breakdown pressure was 1,800 psig and the maximum pressure reached during the frac was 2,200 psig. The average injection rate of frac fluid was 5.6 barrels per minute. Immediately following the completion of the frac a choke was installed on the well equipped with a porcelain lined 1/8 inch diameter choke tube and opened the well to vent the nitrogen, excess sand and foam from the well bore. Successively larger diameter choke tubes were used until finally a 48/64 inch tube was being used. At this time, the flow from the well still maintained good velocity with slugs of slightly sand-laden foam at one to two minute intervals. Flow pressure behind the choke had diminished to zero psig. By the afternoon of November 6, some 26 hours after the frac, the flow had diminished to the point where it was necessary to successively shut the well in for 10 minutes -- during which time the pressure would build to approximately 40 psig -- and reopen the well in order to obtain brief periods of foam recovery. The well was then shut in for approximately 40 hours to allow it to recover enough energy to lift the foam to the surface. This shut-in period resulted in pressure buildup to 1,100 psig and indicated that a considerable amount of nitrogen remained in the well, because the formation gas pressure should not have exceeded 837 psig. Following this buildup and after a one and one-half hour blow through the 48/64 inch choke, the flow diminished to the point where the choke could be removed and the well blown through a 2-inch blow-down pipe. In 18 minutes of flow through the full 2-inch opening, the well showed only a light flow of gas with light showers of foam at frequent intervals but no significant recovery. For a period of 4 additional days, the well was shut in for a build-up period and blown down with results as shown in the following table (Table 5.1).

TABLE 5.1
Flow Back After Stimulation

Date Blown	Initial Pressure	Hours Blown	Result from 2" Blown-down Pipe	Final Pressure
11/08/76	1,100 Psig	2:00	Light showers of foam & sand	0
11/09/76	820 "	2:00	Light showers of foam & sand	0
11/10/76	480 "	2:00	Light showers of foam & sand	0
11/11/76	400 "	2:00	Light showers of foam & sand	0
11/12/76	325 "	2:00	Light foam - flow too low to lift	0

A specific gravity test of the gas from the well was made on November 12, 1976 and a gas gravity of 0.806 obtained. A similar test on the same day of an adjoining well, previously completed in the New Albany Shale by shooting, was made with a result of 0.596 gravity. Comparison of the tests indicated that about 50% of the stream from the well was nitrogen on November 12.

Because of the inability of the well to flow enough gas to lift significant amounts of foam to the surface through the 4½" O.D. casing. Orbit again moved in a small work-over rig and installed a 1-inch siphon line in the well bore on November 20, 1976. The siphon was installed with the bottom perforated nipple set at the base of the shale and 5/64 inch jet nipples spaced to lift fluid to the surface with a minimum of 40 psig well pressure. Use of this siphon to clean up the remainder of the foam from the well was commenced on November 22. The following table (Table 5.2) shows, for each day's operation, the initial shut-in casing pressure before blowing, the amount of time the siphon was open, a summary of the result, and well head pressure on the casing at the end of the blowing period.

* Blew a slug of foam when pressure reached 35 Psig.
** Trace of foam.

As indicated by the data in the above table, the flow from the 1 inch siphon was very low after the initial 5 to 10 minutes of blow. The well, during the 22 hour shut-in interval following each blow, would not build the casing pressure above 150 psig for the last two days. Calculated casing volume at 150 psig is approximately 2 MCF which, if used as a base for the estimate, would indicate an open flow volume for the well at this time of 2 MCF per day. A specific gravity test made from the well head following the cleanup period indicated that practically all of the nitrogen used in the frac job had been removed from the well.

Because of the extremely low productive volume of the well, a long slow buildup in the well head pressure was experienced. On April 13, 1977, after a 115-day shut-in period, the well head pressure was considered to be stabilized and a dead-weight pressure test made. The result of this test was 836.8 psig. A dead weight pressure test on Orbit's adjoining shale gas well (approximately one mile east) made the same day with the same equipment, showed a pressure of 840.6 psig. Both wells were considered to be at a stabilized condition at the time of the tests. The level of pressure obtained from these tests is considered to be approximately equal to the hydrostatic pressure for their depth when related to the surface water table in the area. The pressure as experienced is not an abnormal pressure and conforms to pressure levels usually experienced in various sand reservoir formations in the Western Kentucky area.

On April 15, 1977, and after prior discussions with Mr. Yost of DOE, it was decided to re-stimulate the well using conventional bore-hole shooting. Orbit moved a work-over rig in over the test well, pulled the siphon line, removed the well head, and set 280 quarts of oil-well explosive (nitro) opposite the black shale section from 2,187 ft. to 2,331 ft. No tamping was used. The shot went off at 1:30 p.m. with normal reaction at the surface. Flow from the well after the shot immediately began to settle down, and after one hour was gauged at 40 MCF per day rate. Experience with flow decline over long-term stabilization gained by Orbit in its other shale test in the area indicates that the test well would have an estimated open flow after the shot of 15 MCF per 24 hours.

Following the shot and flow test, the well head was replaced and the well shut-in for five days. Shut-in pressure at this time (April 20, 1977) had build up to 625 psig, and the well was blown through a 2-inch wellhead valve for the purpose of determining if any fluid had accumulated in the hole.

No sign of fluid was noted in the gas stream during this blow down and, although not gauged, the well did not indicate any improvement in flow volume after being blown down. Treatment and pre-treatment data for the first interval is shown in Tables 5.3 and 5.4. Similarly, Table 5.5 presents a summary of the second treatment.

Interval Number/Treatment Number	1/2
Treated Interval	2187' to 2331'
Treatment Date	April 15, 1977
Nitro (quarts)	280
Calculated Open Flow After Shot	15 Mcf per 24 hrs.

6.0 PRODUCTION TESTS

All data indicated that the well should be plugged and abandoned due to the noncommercial gas flow volumes; however, arrangements were made for a temporary gathering system to transport the gas for a period of six (6) months in order to obtain production information.

On June 28, 1977, both the offset and test wells were pressure tested. Specific gravity was measured and a calorimeter test for BTU Content was performed. The results were as follows:

	King Badget #1 (off-set well)	Ray Clark #1 (test well)
Dead weight pressure	839.1 PSIG	834.9 PSIG
Specific Gravity	0.602	0.622
BTU	930	893

Both wells were considered to be at a stabilized condition at the time of the tests. On August 1, 1977 the wells were put into production against a line pressure of approximately 200 psi. Pressure on the gathering system was held back until stabilization occurred and the wells could produce at the line pressure. The pressure of both wells dropped to the 200 psi line pressure by August 5, 1977. The following production has been received:

PERIOD	PRODUCTION (Mcf's @ 15.025 Pressure Base)	
	Clark well	King-Badget Well
August 1-8	202	838
August 9-15	126	546
August 16-22	106	491

Production continued to decline gradually from both wells as indicated. After August 5, 1977 the pressure at which both wells were being produced was from 195 to 200 psi and continued through this date. On August 17, 1977 a sample taken from the common stream of gas from both wells was tested on a calorimeter and indicated 940.0 BTU's and 0.601 specific gravity.

Status of the Well

The well was shut-in, and later plugged and abandoned because of non-commercial gas production.

7.0 SUMMARY OF RESULTS AND CONCLUSIONS

1. The well was cored from 2178' to 2327' and a total of 128 feet of core was recovered. Analysis of the core suggested:
   - Average offgas value in the cored interval was 0.56 cu. ft./ cu. ft.
   - Porosity as determined by the Kerogen Analysis was higher than core porosity.

   No permeability measurements were taken on the cores.
2. The well was stimulated between 2186' to 2320'. Initial open flows were low (2 MCF per day) and no increase in open flow was obtained after stimulation with foam fracturing. A probable reason for failure as suggested by the contractor, was that the formation had extensive natural fractures in the area, and the foam-frac followed the lines of least resistance in this natural fracture system.
3. The well was restimulated using 280 quarts of oil-well explosive (nitro) between 2187' to 2331'. Marginal increases in open flow measurements were obtained (from 2 MCFD to 15 MCFD).
4. Gas production from the well was considered non-economical and the well was later plugged and abandoned.

*Depth below reference level of 548 feet above MSL.

This section includes the physical, chemical, and mechanical properties of the New Albany Shale in Illinois, sampled by Illinois Geological Survey from Ray Clark Well #1. The studies include the quantitative and qualitative characterization, by optical and X-ray techniques, of the inorganic mineral consituents, the dispersed organic mater, and the fabric of the scale. Results obtained are discussed briefly in the following paragraphs.

Chemical Properties

Vitrinite Reflectance

Coals and dispersed organic particles in sedimentary rocks are composed of several distinct components that have been termed macerals by coal petrographers. Macerals differ from one another in their botanical origin, morphology, chemical composition, reflectance, and fluorescence. The reflectance of all macerals varies with the degree of thermal metamorphism (or rank) of the enclosing rock, but the correlation with metamorphism is best exhibited in the reflectance of vitrinite. Vitrinite is an abundant constituent in coal and is frequently present in other types of sedimentary rocks as dispersed grains. It is thought to be derived from woody plant tissues. Because the reflectance of vitrinite changes with small changes in rank, vitrinite reflectance analysis has become a standard technique is studying rank of coal and in evaluating rocks as sources of oil and natural gas.

Vitrinite particles are only a minor component of the organic matter in the New Albany Shale, but they are found in virtually all samples of the black shales. Few vitrinite particles were recovered from the gray-green shales in the New Albany.

Reflectance analysis of the Christian County, Kentucky (01KY) cores has been completed. The data are presented in tables II G 1 and II G 2, and graphically shown on Figure II G I. No significant variation in reflectance with depth was observed in either core. Average reflectance values (Ro) range from 0.33 percent (01KY3C1) to 0.92 percent (1KY4C1), with the majority falling between 0.35 and 0.60 percent Ro. Three samples (1KY4C1, 1KY12C1, and 1KY13C1) have such large standard deviations that they should not be

considered in evaluating the overall formation. The reason for the wide variation in reflectance values for these samples is not yet known. Samples with fewer than 25 readings should be considered only approximate indicators of the reflectance at that level. Fifty readings is usually considered an adequate sampling.

The average reflectance values for the Kentucky core are near 0.5 percent, while those of the Illinois core are near 0.4 percent. This difference may not be significant. The absence of a vertical reflectance gradient implies that the geothermal gradient in these two areas was fairly low. The reflectance values observed in these cores correspond to a level of organic metamorphism of 2 to 8 (LOM scale of Hood et al., 1975*). Studies by petroleum geologists have related this range to the stage of early methane generation, resulting from biologic and other low-temperature processes. The main phase of gas generation occurs at LOM values of 12 to 14, corresponding to vitrinite reflectances of 1.4 to 2.1 percent Ro (see Fig. II G 3).

Clay Mineral Orientation

Clay orientation analyses for the OlKY is presented in Table II G 3 and in Figure II G 4. The linear trend of orientation vs. depth observed in the upper portion of the core does not continue to the base of the formation. The break in this trend at 2300 feet approximately coincides with the base of the Morgan Trail Member. The underlying Blocher Member is a finely laminated black, pyritic shale most similar to the shales at the top of the core.

An orientation index of 1.0 corresponds to a completely random fabric. Higher values correspond to increasingly more perfect alignment of the clay flakes in the shale. The high values measured are associated with the finely laminated fissile black shales; low values are associated with poorly to nonlaminated gray and dark-gray shales.

Table 11 G 4 exhibits that data of clay mineral analyses by using X-ray mineralogy technique.

Thin-Section Petrography

Oriented horizontal thin sections were prepared to the directional

properties and Paleocurrent indicators. Few elongated particles were found suitable for measurement, within the standard 1" x 2" petrographic slide. Several random particles were found which may indicate: (1) the absence of bottom currents that would serve to orient the particles, (2) shifting bottom currents that oriented the particles in several directions, or (3) the reorientation of particles by compaction or other nondepositional processes.

Microfossils

The thin section made at the depth of 2231 feet, reveal the presence of calcareous microfossils. These microfossils as identified are calcispheres of the genus Radiina Reitlinger. The carbonate that makes up the calcispheres is pleoehroic and stands out distinctly in the thin section. Very little is known about the paleoecology of calcispheres, and their relationship to the depositional environment of the shale is at present unknown.

Mechanical Properties

This includes the point load fracture strength.

Point Load Testing

Values of the point load index have shown a sizeable range: black shales, 1.32 to 4.89 MPa; limestones, 3.20 to 10.80 MPa. In addition, there seemed to be considerable deviation from the original axial loading of the sample during failure. However, the orientations of the fractures have shown the following apparent preferred orientations:

Lithology	Location	Orientation
Black Shale	Upper New Albany	$140^{o}/320^{o} \pm 25^{o}$
Black Shale	Lower New Albany	$95^{o}/275^{o} \pm 15^{o}$
Limestone	Below New Albany	$170^{o}/350^{o} \pm 40^{o}$

Adsorption/Desorption Studies of Gases Through Shales

With nitrogen and carbon dioxide, determine internal surface area on 900 shale core samples; on 100 of these, use methane as the absorbate. Determine methane adsorption isotherms for the 100 shales at pressures within the range of 1 to 80 atmospheres. Comparison of these properties in gas-producing and non-gas-producing shales will be made to determine the relationship of shale physical properties to gas recovery.

Christian County, Kentucky, Core

Isotopic analyses were performed on methane from four of the gas samples from the Christian County, Kentucky core (01KY), and the results are given in Table 3. These values are typical of gas of low to moderate maturity, formed by thermal degradation of organic matter. Sample 2, however, is isotopically much heavier (i.e., a higher C^{13}/C^{12} ratio and a more positive C^{13} value) than the others, and the C13 value obtained is typical of relatively mature gas, such as that produced in the Gulf Coast regiona and the south-central U.S. This value appears to be anomalous when compared to the others from the same core.

Table 3. Carbon-isotopic composition of methane from core 01KY. Compositions are expressed relative to the PDB standard. The precession is $\pm$ .5 $^{o}/oo$.

Sample	C^{13} $^{o}/oo$
2C1	-41.7
4C1	-48.5
7C1	-49.1
11C1	-49.4

Stahl (1974) has developed a model based on laboratory studies and analyses of gas samples from several areas of the world that relates the isotopic composition of methane to the hydrocarbon composition of the gas. According to the model, the first methane that is formed in a sedimentary environment is the result of bacterial degradation of organic matter. The

only hydrocarbon component formed is methane, and the methane is isotopically very light (C^{13} = -65 to -90 $^{o}/oo$). With deeper burial and increasing temperature, bacterial degradation of organic matter is replaced by thermal degradation. The first gas formed by this process is also primarily methane, but as the process continues and the temperature increases (i.e., increasing maturity), the proportion ofheavier hydrocarbons (i.e., C_2H^6, C^3H^8, C^4H^{10}, etc.) formed increases. This continues until a point is reached where even the heavier hydrocarbon gases begin to break down to methane, and the methane content of the gas again increases. Throughout the process the methane continually becomes isotopically heavier. This model is illustrated by the stippled region on Figure 1.

The four points shown on Figure 1 represent the samples from core OlKY. The four samples have compositions very close to those predicted by the model and suggest that the gas from sample 2 is more mature tha that from the other samples.

To determine if this trend is apparent throughout the core, and not just in these four samples, we plotted Figure 2, which shows the hydrocarbon composition of 12 samples from the core, as a function of depth. This plot shows that there is a general trend of increasing methane content with depth. This implies that maturity increases from the bottom to the top of the core and is opposite to what one would normally expect. In fact, since we are dealing with only about 100 feet of core, one would expect little if any difference in maturity between the samples.

The vitrinite reflectance data, presented elsewhere in this report, are an indication of the maturity of the solid organic material in the sediments. These data suggest that the organic material is relatively immature and that the maturity is fairly constant throughout the section of the core studied. The data support the previous implication that the isotopic and chemical data suggest an anomalous situation.

One possible explanation that is presently being investigated is that in the area where this core was taken, gas has migrated out of the shale into the overlying strata. When gases flow through porous materials via diffusional processes, the different components may migrate at different rates. In most cases, the lighter components migrate more rapidly. If gas has been migrating out of the shale very slowly over a long period of time, one would expect the gas remaining to be enriched in the heavier

components (i.e., $C^{13}H_4$ relative to $C^{12}H_4$, C_2H_6 relative to CH_4, etc.). Also if the migration were upward, the upper portion of the shale would be more affected than the lower portion.

THis hypothesis appears to fit the data that have thus far been considered; however, a more thorough analysis of all available data is necessary before a conclusion can be drawn.

APPENDIX F

This section includes the copies of the logs provided by Schlumberger Well Services. They include:

- Sonic Log
- Compensated Neutron Formation Density Log
- Microlaterolog - Microlog
- Dual Induction - Laterolog
- Coriband Analysis

APPENDIX G

This section contains the scope of work for the Orbit Gas Company Eastern Gas Shale Project Contract

UGR File #254
SAI
July 1979

SCOPE OF WORK

Eastern Gas Shales Project - Concept for
Stimulating Production From the Upper
Devonian Shale of Western Kentucky

1.0 Work under this contract shall be performed in accordance with the specific tasks of effort set forth below. The total project shall consist of 3 tasks which shall be performed sequentially. The objective of the project is to 1) acquire oriented core material and comprehensive geophysical well log data from the Devonian Shale in western Kentucky and 2) to evaluate the technical and economic feasibility of stimulating natural gas production from the Devonian Shale by hydraulic fracturing. The Contractor shall furnish the personnel, facilities, equipment and services necessary to perform each task of the program as outlined below.

1.1 Task 1 - The Contractor shall select a well location in the East Crofton Field of Christian County, Kentucky. More specifically, the well will be located in the southeastern portion of Section 9, Township 6, Range 25, and will be as close to Highway 800 as possible. Once the well location has been selected, a map showing the location will be supplied to the ERDA TPO. The Government shall have two (2) working days after receipt of the map to concur with the Contractors selection or to make recommendations concerning an alternate location. No work shall commence or costs be incurred for subsequent tasks work until written authorization to proceed with these tasks has been granted by the Contracting Officer.

1.2 Task II - The Contractor shall obtain all the necessary state and local permits and satisfy all existing state and local laws and regulations pertinent to the drilling of a natural gas well in Christian County, Kentucky.

The Contractor shall then drill, core, log and case a well through the Devonian Shale formation. The Contractor will drill and case the hole, using standard field practices, in such a manner that satisfies all existing state and local laws and regulations. Conventional drilling will continue to the top of the New Albany Shale at an approximate depth of 2000 feet. This depth will be referred to as the "core point". The Contractor will use all available information to select the core point as accurately as possible.

A four inch diameter oriented core will be obtained through the entire (approximately 200 ft.) Devonian Shale formation. The core material will be handled, i.e. marked, wrapped, boxed and transported, by MERC/ERDA personnel. The core material will be transported to MERC where it will be processed for utilization in the Eastern Gas Shales Project (EGSP).

Following the coring operation, a comprehensive suite of geophysical well logs will be run in the well. This suite of logs will be consistent with the logging program outlined in the EGSP and will consist of the following logs:

(1) Gamma Ray
(2) Formation Density Compensated
(3) Temperature
(4) Caliper
(5) Sibilation
(6) Dual Induction - Laterolog
(7) Micro Laterolog
(8) Compensated Neutron
(9) Sonic
(10) SP

After the logging operation is complete the Contractor shall case the hole through the Devonian Shale with K-55, 4-1/2 O.D. seamless casing. The cement top shall be at least 200 feet above the top of the Devonian Shale formation.

The Contractor and the ERDA TPO and/or his representative shall concur on the hydraulic fracturing design for this well. The placement of the perforations and the exact size of the treatment will be determined using data from drilling records, core analysis, and well logs. The hydraulic fracturing fluid will be sand-laden foam - 75% nitrogen, 25% water. Approximately 1200 barrels of foam, and 50,000 pounds of 20-40 mesh sand will be used in the fracturing operation. This quantity of fluid and proppant is consistent with other experimental stimulation work that is being conducted in conjunction with the EGSP.

The final design of the hydraulic fracturing treatment will be prepared by ERDA and sent to the Contractor for concurrence no later than 20 working days after the logging operation has been completed. The Contractor shall have five (5) working days to approve the design or make recommendations concerning an alternate design. No work shall commence or costs be incurred for subsequent tasks work until written authorization has been granted by the Contracting Officer.

1.3 Task III - The Contractor shall hydraulically fracture the well according to the design approved in Task II. Due to certain unknown reservoir parameters it may be necessary to make changes in the hydraulic fracture treatment while the treatment is in progress. The ERDA TPO will be on location to make recommendations and to concur with any proposed changes.

Due to the critical nature of the "flowback" period after the treatment the ERDA TPO and/or his representative will be present to advise the Contractor on the procedures that must be followed to produce the best results.

Once well conditions permit, the Contractor shall conduct extensive well tests which will permit evaluation of the hydraulic fracture treatment. These tests will consist of a four-point, modified-isochronal test, a drawdown test, and a long-term pressure build-up test.

The Contractor shall prepare and present to the ERDA TPO a final report which contains a log of all wellsite activities, results, and recommendations through the end of the preliminary testing and evaluation period.

1.4 Task IV - If production is sufficient from the proposed well and other developmental wells to warrant laying a gathering line to this field, the proposed well will be put on line and its production monitored for a three year period. Monthly production records will be supplied to the ERDA TPO semi-annually. These records should include amount of gas produced, wellhead pressures and the composition of the gas being produced.

Deliverables

As part of the work to be performed pursuant to this contract, the Contractor shall submit the following reports:

1.0 TASK REPORTS

The Contractor shall prepare and submit a letter report at the completion of each task of effort. This report shall provide a narrative summary of all work accomplished under each task including conclusions reached and specific recommendations for subsequent tasks effort.

2.0 DRAFT FINAL REPORT

Upon completion of the work described in the Statement of Work, the Contractor shall prepare and submit a draft final report which shall include an analysis of salient findings, a presentation of general conclusions, and any guidance or recommendations deemed pertinent for future consideration by the Government. The Government will be allowed twenty (20) days to review the draft and notify the Contractor, in writing, of approval or of recommended changes to be made in the final copy.

If the Government does not approve or recommend changes in writing within twenty (20) days of receipt of the draft final report, the report will be deemed approved. The draft final report shall also include a list of inventions made or conceived in the course of or under the contract or a certification of the absence thereof.

3.0 FINAL REPORT

Within thirty (30) days of receipt of approval of the draft final report from the Government Technical Project Officer, the Contractor shall furnish the Government with a reproducible master and the required number of copies of the final report in final form. For the reproducible master, the typing shall be single spaced on one side of the sheet only, and all photographs shall consist of glossy prints.

The following disclaimer shall be printed or stamped on the title page or inside cover of each volume and copy of the final report:

> "The views and conclusions contained in this document are those of the authors and should not be interpreted as necessarily representing the official policies or recommendations of the U.S. Government."

DELIVERY DATES

1. Reports

Description	Quantity	Delivery Date
a. Task Reports	10 copies	Due on or before ten (10) days after the completion of each task of effort
b. Draft Final Report	10 copies	Due ten (10) days after completion of Task IV
c. Final Report	One reproducible master and 50 copies	Due on or before thirty days after approval of the draft final report.

2. Distribution of Reports

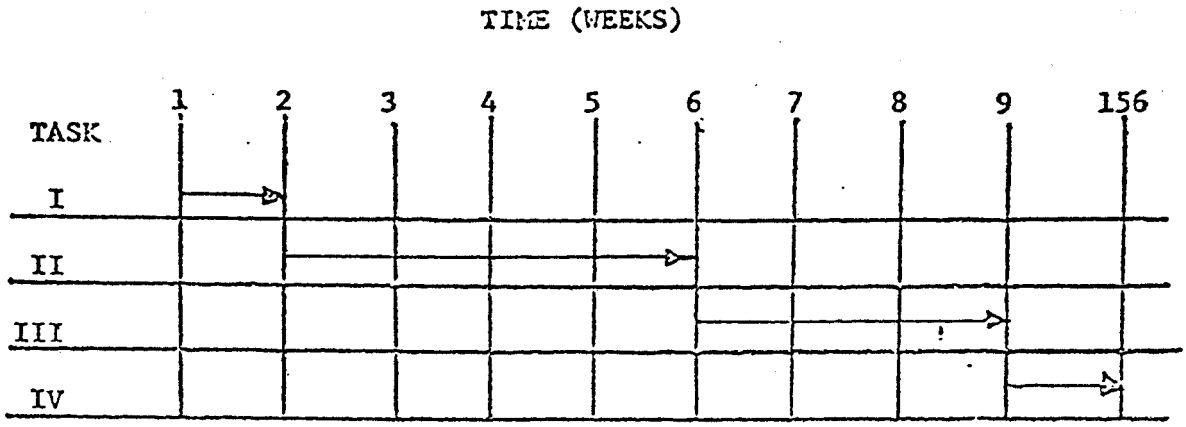
a. One copy of each report, in draft and/or final form, as required by this contract, shall be delivered prepaid to:

United States Energy Research and Development Administration
P.O. Box E
Oak Ridge, Tennessee 37830

ATTENTION: F. O. Christie, Director, Contract Division
Oak Ridge Operations

b. All remaining copies of reports shall be delivered prepaid to the Government Technical Project Officer designated by the Contracting Officer.

TASK SCHEDULE



APPENDIX H

This section contains a monthly financial report, an oil and gas lease, permit to drill, and examination of the title to the leasehold estate performed by Neal & Neal Attorneys, and bid sheet and well specifications.

AN GAS LEASE
Kentucky Form

596

AGREEMENT made and entered into this _____ day of _____ 19__

between J. Ray Clark and Georgia M. Clark (his wife)
Box 208, Crofton, Kentucky

the first part, hereinafter called lessor (whether one or more) and Orbit Gas Company
711 Leitchfield Road, Owensboro, Kentucky

_____ party of the second part, hereinafter called lessee.

WITNESSETH, That the lessor, for and in consideration of Twenty-Five Hundred 00/100 DOLLARS ($ 2,500.00 hand paid, the receipt of which is hereby acknowledged, and of the covenants and agreements hereinafter contained, has granted, demised, leased and let, and by these presents do exercise, lease, and let exclusively unto the said lessee, its successors and assigns, the land hereinafter described, with the exclusive right for the purpose of mining, exploring b cal and other methods, and operating for and producing therefrom oil, gas, casing-head gas, casing-head gasoline, and the exclusive right of injecting water, brine and other fluid surface strata, with rights of way and easements for laying pipe lines, telephone and telegraph lines, tanks, power houses, stations, gasoline plants, ponds and roadways and fixtu cing, treating, and caring for such products and housing and boarding employees and any and all other rights and privileges necessary, incident to, or convenient for the economic alone or con-jointly with neighboring land, on said land for the production of oil, gas, casing-head gas, casing-head gasoline, and erection of structures thereon to produce, sa ing of said products, and the injecting of water, brine and other fluids into subsurface strata. All that certain tract of land situated in the _____ County of Christian, State of Kentucky, and bounded as follows, to-wit:

On the North by lands of Highway #800
On the East by lands of Henry L. King
On the South by lands of Lawson West, Wallace King and C. B. Zentmyer
On the West by lands of C. B. Zentmyer, W. Craddick
Containing 481 acres, more or less, and being the same land conveyed to lessor by Joe P. Clark

_____ deed dated _____, recorded in Deed Book 7 Page 543
_____ deed dated May 10, 1948, recorded in Deed Book 247 Page 389
County Clerk's Office

It being intended hereby to include herein all lands and interests therein contiguous to or appurtenant to said described lands owned or claimed by lessor. For rental payment purpose sed lands shall be deemed to contain 481 acres.

It is agreed that this lease shall remain in force for a term of two years from this date and as long thereafter as oil, gas, casing-head gas, casing-head gasoli there is produced from said leased premises or operations for drilling are continued as hereinafter provided, or operations are continued for the injection of water, brine and oth to subsurface strata. Provided, however, that for injection purposes this lease shall continue in full force and effect only as to well or wells so used and the ten acres contiguo

consideration of the premises the said lessee covenants and agrees:

1. To deliver to the credit of lessor, free of cost, in the pipe line to which lessee may connect his wells, the equal one-eighth part of all oil produced and saved from the lease or at the lessee's option, may pay to the lessor for such one-eighth royalty, the market price for oil of like grade and gravity prevailing on the day such oil is run into the pip into storage tanks.

2. To pay lessor one-eighth, at the market price at the well for the gas so used, for the gas from each well where gas only is found, while the same is being used off the premises, a to have gas free of cost from any such well for all stoves and inside lights in the principal dwelling house on said land during the same time by making his own connections with th his own risk and expense.

3. To pay lessor for gas produced from any oil well and used off the premises or for the manufacture of casing-head gas, one-eighth, at the market price at the well for the gas the time during which such gas shall be used, said payments to be made monthly.

If no well be commenced on said land on or before one year from date hereof, this lease shall terminate as to both parties, unless the lessee, on or before th shall pay or tender to the lessor's credit in the Planters Bank & Trust
Hopkinsville, Kentucky, or its successors, which shall continue as the depository regardless of changes in the ownership of said land, the s $962.00 Dollars, which shall operate as a rental and cover the privilege of deferring the commencement of a well for twelve mont date. In a like manner and upon like payments or tenders the commencement of a well may be further deferred for like periods of the same number of months successively. All paymen tenders may be made by check or draft of lessee or any assignee thereof, mailed or delivered on or before the rental paying date.

If no well the first well drilled on the above described land be a dry hole, then, and in that event, if a second well is not commenced on said land within twelve months from the expirati the last rental period for which rental has been paid this lease shall terminate, as to both parties, unless the lessee on or before the expiration of said twelve months shall resume t of rentals in the same amount and in the same manner as hereinbefore provided. And it is agreed that upon the resumption of the payment of rentals, as above provided, that the la paragraph hereof, governing the payment of rentals and the effect thereof, shall continue in force just as though there had been no interruption in the rental payments.

If said lessor owns a less interest in the above described land than the entire and undivided fee simple estate therein, then the royalties and rentals herein provided shall be paid t or only in proportion which his interest bears to the whole and undivided fee.

Lessee shall have the right to use, free of cost, gas, oil and water produced on said land for its operation thereon, except water from wells of lessor.

If requested by the lessor, lessee shall bury its pipe lines below plow depth.

No well shall be drilled nearer than 200 feet to the house or barn on said premises, without the written consent of the lessor.

Lessee shall pay for damage caused by its operation to growing crops on said lands.

Lessee shall have the right at any time to remove all machinery and fixtures placed on said premises, including the right to draw and remove casing.

If the lessee shall commence to drill a well within the term of this lease or any extension thereof, the lessee shall have the right to drill such well to completion with reasonal and dispatch, and if oil and gas, or either of them, be found in paying quantities, this lease shall continue and be in force with like effect as if such well had been complet the term of years herein, first mentioned.

If the estate of either party hereto is assigned, and the privilege of assigning in whole or in part is expressly allowed, the covenants hereof shall extend to their heirs, executor rators, successors or assigns, but no change in the ownership of the land or assignment of rental or royalties shall be binding on the lessee until after the lessee has been furnish written transfer or assignment or a true copy thereof; and it is hereby agreed in the event this lease shall be assigned, as to a part or parts of the above described lands and t or assignees of such parts shall fail or make default in the payment of the proportionate part of the rents due from him or them, such default shall not operate to defeat or af e in so far as it covers a part or parts of said lands which the said lessee or any assignee thereof shall make due payment of said rental.

If the leased premises are now, or shall hereafter be, owned in severalty or in separate tracts, the premises nevertheless shall be developed and operated as one lease, and all royalt ruing hereunder shall be treated as an entirety and shall be divided among, and paid to such separate owners in the proportion that the acreage owned by each separate owner bears to leased acreage: Provided however, if the leased premises consist of two or more non-abutting tracts this paragraph shall apply separately to each such non-abutting tract and furt that if a portion of the leased premises is hereafter consolidated with other lands for the purpose of operating the consolidated tract as one lease this paragraph shall be incope o such portion so consolidated.

If at any time there be as many as four parties entitled to rentals or royalties, lessee may withhold payments thereof unless and until all parties designate in writing in a recorda t to be filed with the lessee, a common agent to receive all payments due hereunder; and to execute division and transfer orders on behalf of said parties and their respect essors in title.

Lessee is hereby given the right and power to pool or combine the acreage covered by this lease or any portion thereof with other land, lease or leases in the immediate vicinity there lessee's judgment it is necessary or advisable to do so in order properly to develop and operate said premises in compliance with the spacing rules of any lawful authority, or when ld, in the judgment of the lessee, promote the conservation of the oil and gas in and under and that may be produced from said premises. In connection with the production of oil s ay be in a unit or units not exceeding 50 acres each. In connection with the production of gas such pooling may be in a unit or units not exceeding 320 acres each. Lessee sh n writing an instrument identifying and describing the pooled acreage. The entire acreage so pooled into a tract or unit shall be treated, for all purposes except the payment ties on production from the pooled unit, as if it were included in this lease. If production is found on the pooled acreage, it shall be treated as if production is had from this lea r the well or wells be located on the premises covered by this lease or not. In lieu of the royalties elsewhere herein specified, lessor shall receive on production from a unit only such portion of the royalty stipulated herein as the amount of his acreage placed in the unit or his royalty interest therein bears to the total acreage so pooled in the particu lved. Provided, lessee shall be under no obligation whatsoever, express or implied, to drill more than one well to each such unitized tract, regardless of when, where or by w lls may be drilled.

In the event gas is discovered on the leased premises, it is agreed that during any period when, after the discovery of gas on the leased premises, gas is not being sold on account of market, and if there is no apparent production or operation on said lands sufficient to keep this agreement in full force and effect, the LESSEE may pay as royalty Fifty Doll .00) per year for each shut-in gas well, and such payment will be considered as if gas is actually being produced within the terms and conditions of this oil and gas lease. Such payn be made annually in advance, within ninety (90) days following the completion of the well or the cessation of a market for gas. Such payment shall be paid or tendered to the LESSOR the depository bank to be specified by the LESSOR. No rental shall accrue as to the leased premises during any period covered by a shut-in gas payment as herein provided. The shut-in herein provided for shall be considered advance royalties, and production from the leased premises during any annual period for which shut-in gas rental or royalty has been paid ed against such advance payment.

Lessor hereby warrants and agrees to defend the title to the lands herein described, and agrees that the lessee shall have the right at any time to redeem for lessor, by payment taxes, taxes or other liens on the above described lands, in the event of default of payment by lessor, and be subrogated to the rights of the holder hereof and lessor hereby agrees t such payments made by the lessee for the lessor shall be deducted from any amounts of money which may become due the lessor under the terms of this lease.

The undersigned lessors, for themselves and their heirs, successors and assigns, hereby surrender and release all rights of dower and homestead in the premises herein described insofar said rights of dower and homestead may in any way affect the purpose for which this lease is made as recited herein.

Should the depository bank hereafter close without a successor, lessee or his assigns may deposit rentals in any National Bank located in same county with first named bank, due notice deposit of such rental to be mailed to the lessor at last known post office address.

~~Lessee shall have the right to use gas and water free in any stone underlying the premises. Oil wells may be drilled and drilled for oil~~
~~If oil or gas in paying quantities for the entire lease shall be found, lessee shall pay to lessor as annual rental of One Hundred Dollars ($100.00) per well payable annually~~

All express or implied covenants of this lease shall be subject to all Federal and State Laws and to all executive orders, rules or regulations of State and Federal authorities and shall not be terminated, in whole or in part, nor lessee held liable for any failure to perform thereunder if such failure is due or is the result of any such law, order, rule gulation.

AUTHORITY TO DRILL, DEEPEN, OR REOPEN A WELL

Permit No. 31175
Elevation 543.91
County CHRISTIAN

Lexington, Ky., AUGUST 12, 1976

This is the authority under the 1960 Oil and Gas Conservation Act, effective June 15, 1960, and the Rules and Regulations of this Division, for ORBIT GAS COMPANY 711 LEITCHFIELD ROAD OWENSBORO, KENTUCKY 42301 to drill a well on the below described premises.

Location of well to be 12-G-25 650' FNL X 90' FEL

Said well is number 1 (GAS) and lessor is J. RAY AND GEORGIA H. CLARK

This permit expires one year from date of issuance unless drilling operations have commenced, prior thereto.
A log of this well must be furnished to the Oil & Gas Division, at Lexington, Ky., in compliance with the laws of the Commonwealth of Kentucky.

This permit must be posted at the well site before drilling commences.

EXHIBIT "C"

EXCEPTIONS AND REQUIREMENTS

Exception (1): This opinion is subject to any easements, defects and rights of parties in possession a survey or visual inspection of the premises would disclose and does not certify against overlapping senior patents or surveys.

The fourth call of the current deed description is S 10 W 134 poles. Apparently this should be S 10 E 134 poles, which is the call we have used in Exhibits A and B.

Requirement: Affidavit of Adverse Possession using the correct description.

Exception (2): This opinion covers only the 222 acre tract described in Exhibit A and shown on Exhibit B.

Requirement: Supplemental title examination and opinion prior to drilling operations on the remaining portions of the lease.

Exception (3): On November 11, 1963, Deed Book 298, page 191, J. Ray Clark and Georgia Clark, his wife, conveyed the Commonwealth of Kentucky, Department of Highways, a strip 30 feet on each side of the proposed centerline of the Crofton Apex Road, plus additional footage at points thereon.

Requirement: None.

Exception (4): Master Commissioner's Deeds in the Christian County Court Clerk's office are indexed in the name of the grantees only in Commissioner's Deed Books 1 through 8 and in the name of the Master Commissioner and grantee in Commissioner's Deed Book 9, therefore this opinion excepts any Master Commissioner Deeds not disclosed in the chain of title upon which this opinion is based.

Requirement: None.

Exception (5): We found several old oil and gas leases covering the captioned tract, the most recent being a lease from J. R. Clark and Georgia M. Clark, his wife, to Fairy D. Yundt, August 4, 1964, for a primary term of one (1) year.

Requirement: Affidavit of Non-Production.

LAND COVERED:

Bounded as follows:
On the North by Highway #800
On the East by Henry L. King
On the South by Lawson West, Wallace King and C. B. Zentmy
On the West by C. B. Zentmyer, W. Craddick.
Containing 481 acres, more or less.

RECORDS EXAMINED

This opinion is based on a personal examination of the relevant and properly indexed records of Christian County, Kentucky, for a period of over 156 years, ending with the date hereof, and covers land located in Christian County, Kentucky, more particularly bounded and described in the following exhibits:

Exhibit A - Metes and bounds description and source of title.
Exhibit B - Plat of subject tract.

OPINION

In reliance upon the relevant and properly indexed records of Christian County, Kentucky, for the period aforesaid, subject to the exceptions and requirements hereinafter set out and any defects a survey or visual inspection of the premises may reveal, we are of the opinion that the title to the subject tract is vested as follows:

SURFACE AND MINERALS

Georgia M. Clark and J. Ray Clark, her husband, and the survivor of them	ALL

ROYALTY INTEREST

Georgia M. Clark and J. Ray Clark, her husband, and the survivor of them	1/8 RI

WORKING INTEREST

Orbit Gas Company	7/8 WI

Re: J. Ray Clark, et ux
481 Acre Lease
Christian County, Kentucky
11 & 12-G-25

Gentlemen:

Pursuant to your request, we have examined the title to the leasehold estate created by the following described oil and gas lease:

FORM OF LEASE:	Producers 88 SP. T.O.P. Rev.
LESSORS:	J. Ray Clark and Georgia M. Clark, his wife
LESSEES:	Orbit Gas Company
DATE OF LEASE:	December 4, 1975
RECORDED:	December 11, 1975, Lease Book 29, page 596, Christia County Court Clerk's office
PRIMARY TERM:	Two (2) years
ROYALTY:	One-eighth (1/8)
DELAY RENTAL PROVISION:	If no well be commenced on said land within one (1) year from date hereof, lesso shall pay to lessor the su of $962.00, or this lease shall terminate.
DEPOSITORY:	Planters Bank & Trust Hopkinsville, Kentucky
SPECIAL PROVISIONS:	None.

CONCLUSION

In reliance upon the relevant and properly indexed records of Christian County, Kentucky, for the period aforesaid, subject to the exceptions and requirements hereinabove set out and any defects a survey or visual inspection of the premises may reveal, we are of the opinion that title to the subject tract is vested as hereinabove set out.

Very truly yours,

NEAL & NEAL

APPENDIX I

This Section contains a narrative account of the Coring Operations

UGR File #254
SAI
July 1979

SUMMARY OF CORING OPERATIONS

ORBIT GAS COMPANY

WELL

Ray Clark No. 1

Christian County, Kentucky

Prepared by C. S. Dean, Ph.D.

Geologist, ERDA-MERC

The following summary of coring operations for the Orbit Gas Company well Ray Clark No. 1 includes a narrative account, a generalized description of the core, and some recommendations. The well is located 600 ft. south of Kentucky route 800, 3½ miles due east of the town of Crofton in Christian County, Kentucky. The exact location, as stated in the permit (no. 31175), is 12-G-25, 650' FNL x 90' FEL (Carter Coordinate System). The well was drilled by the Crescent Drilling Company of Owensboro, Ky. on Quebracho, Polymer mud (Dextrid) having a weight of 8.9 lbs/gal., a viscosity of 38 sec./qt., and a water loss of 3.6 ml./min over the duration of a 30 min. test. The nominal diameter of the hole upon reaching core point was 7 7/8 in. Since the outside diameter of the core bit was 7 27/32 in., it was assumed that no reaming of the hole would be necessary prior to coring. The well was cored under the supervision of Christiansen Diamond Tool Company. The core retrieved is 4 in. in diameter. All logging is relative to the top of the kelly table, which stands at an elevation of 548 ft. above sea level.

Narrative Account

Friday, September 17, 1976.

The MERC petroleum engineer (H. Koerner) and geologist (C.S. Dean) arrived at the drill site around 9:30 a.m. Core point had been reached at 9:00 a.m. and the drilling fluid was being circulated in order to flush out any cuttings remaining in the hole. Mr. Donald Benson, President of Orbit Gas, who had closely monitored drilling operations as core point was approached, explained the criteria he used to pick the core point: drilling rate and cuttings.

In western Kentucky the New Albany Fm. (the name for the Devonian Black Shale in the Illinois Basin) of Upper Devonian age is sequentially overlain by the New Providence Shale and the Fort Payne Formation both of Lower Mississippian age. The systemic boundary is placed at the contact between the New Providence Shale and the New Albany Formation. Drilling was halted following the appearance of limestone within the cuttings of the New Providence Shale. A thin interval of limestone, the Rockford Limestone, occurs at the base of the New Providence Shale, i.e., immediately overlying the New Albany Shale. Subsequently, circulating drilling fluid brought up cuttings of balck shale. Mr. Benson placed the upper contact of the New Albany Shale at 2175 ft.; drilling ceased at 2178 ft.

Mr. Bensen had expected the Rockford Limestone to be 20 feet thick instead of only one foot thick; this was the reason for drilling three feet into the shale.

The drill string was hauled up and a ring gage slipped over the drill bit. The bit, a retip, was badly out of gage. The core barrel and monel collar orienting apparatus were then assembled by Christiansen Technicians and lowered into the hole under their supervision. At 928 ft. a hang up occured; the drilling log revealed that at this depth the drilling contractor had changed drill bits. Randall Anselment of Christiansen gave the driller permission to use the core bit to ream out the obstruction. Reaming past the obstruction was speedily and easily accomplished; the remainder of the descent was without incident. Coring began at 5:50 p.m. (at a depth of 2178 ft.)

Saturday, September 18, 1976

During the night, at 2215 ft., an incident occurred that resulted in the loss of some 23 feet of core. The slips located within the core bit that are designed to catch the core and prevent it from falling back down the hole failed to grip properly when the string was lifted off the bottom in order to make a connection. Instead of lifting the core, the core barrel slid over the core while the core remained in place. On the return trip back down to the bottom of the hole, the core barrel recaptured most of the core but jammed 21 ft. above the bottom of the hole. Christensen directed the core barrel be raised.

At 7:00 a.m., while on the way out of the hole with the first length of core, the string jammed at a depth of 1675 ft. It remained jammed until about mid afternoon, when it finally pulled free with the exertion of 160,000 - 180,000 lbs. of steady pull on the string. The pull that finally freed the string was effected by placing the lifting engines into direct, locked drive. Excessive mud cake was blamed for the hang up that occurred on the way out of the hole. Hole out of gage and faulty rig procedure may have been contributing factors. Once freed the remainder of the string was raised with relative ease.

The core barrel emerged about 5:30 p.m. D. L. Stevenson of the Illinois State Geological Survey (ISGS) removed the core from the core barrel under the supervision of H. Koerner, the MERC petroleum engineer. The first length of intact core was 14 ft. long; rubble comprising perhaps an additional 2 ft. at the bottom was also recovered. The core was broken down into manageable lengths, placed into short wooden boxes, and transferred to the Christensen trailer, where it was laid out and reassembled. After wiping the core down with a damp rag, J. A. Lineback (ISGS) logged the geological features. He was assisted by C. S. Dean (MERC). Subsequently, outgassing samples were removed and canned according to instructions in Task Order 2102. Finally, the core was placed into cardboard boxes and stowed aboard ISGS vehicles for shipment to ISGS. Mylar bags specified in the task order were not available on the site.

Because of the difficulties experienced in raising the first length of core, the operator reconditioned the hole prior to the second coring run; reconditioning included drilling up the 21 feet of core lost in the hole.

Sunday, September 19 to Monday, September 20, 1976.

The second length of New Albany Shale core emerged without incident around midnight. This core measured 59.5 ft. in length. Procedures followed were identical to those described above.

Monday, September 20 to Tuesday, September 21, 1976.

The third length of core emerged without incident around midnight, having penetrated 11 feet into the Sellersburg Limestone, the Middle Devonian limestone directly underlying the New Albany Shale. Coring ceased at 2331 ft. when the bit struck a layer of chert. This core measured 56 feet. Handling and logging procedures were the same as with the first two cores.

Following the taking of the third core the operator returned to drilling; Mr. Benson (Orbit Gas) expressed the intent of going down 225 to 250 feet more before completing.
