

## Pressure Gain Combustion for Land Based Power Generation

**NETL – Office of Research and Development (ORD) and Advanced Energy Systems Program (AES)**  
*Providing Clean Energy Technology Through Innovative Ideas*

Don Ferguson (PhD)

Todd Sidwell, Pete Strakey (PhD), Arab Roy (PhD), Andrew Sisler

# Cost of Carbon Capture

David, J. and Herzog, H., "The Cost of Carbon Capture", NETL Workshop on Carbon Capture, 2001

- **Comparative analysis of the increased Cost of Electricity with 90% capture**
  - PC and NGCC with post-combustion MEA capture
  - IGCC with pre-combustion absorption
- **Analysis considers the sensitivity of COE to changes in parameters such as Heat Rate (fuel consumed)**
  - For a 10% decrease in fuel consumed (Heat Rate) for NGCC with CC, estimated COE would decrease by 13%
- **Subsequent benefit of reducing the size of the CC with a reduction in fuel consumed**

Difference from Ref with no capture.	PC	NGCC	IGCC
Therm Efficiency (%Change)	-6.3%	-6.0%	-4.3%
COE (% Change)	+53%	+40%	+25%

Decrease in COE with 10% decrease in parameter. A 10% decrease in HR could have a 13% decrease in COE for NGCC.

# DOE/NETL Turbines Program

- **Manages a research, development, and demonstration (RD&D) portfolio of projects designed to remove environmental concerns about the future use of fossil fuels through development of revolutionary, near-zero-emission advanced turbine technologies.**

## **Advanced combined cycle turbine**

- Applicable to natural gas and H<sub>2</sub>
- T3 of 1900 K
- Adv. components: pressure gain combustion, advanced transition, air foils w/ decoupled thermal & mechanical stresses
- Delivers another \$20/T reduction in CO<sub>2</sub> capture cost
- NG CC (LHV) efficiency approaching 65%

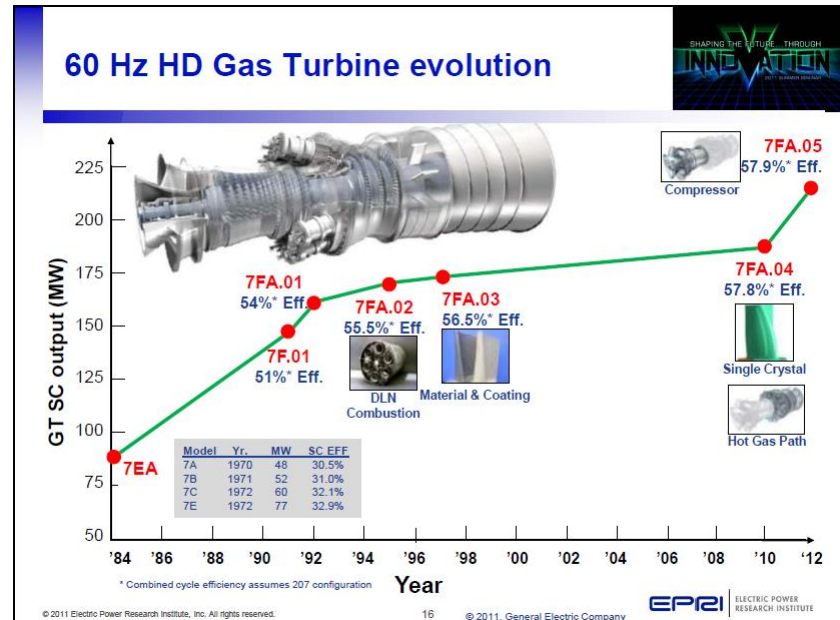

# Gas Turbine Technology Development

## *Evolution to Revolution*

- Recent technology advancements have resulted in incremental improvements in efficiency. For example consider the GE F class engine.

Model	Year	CC Eff	Technology
7FA.01	1992	54%	Combined cycle advancement
7FA.02	1995	55.5%	DLN Combustion
7FA.03	1997	56.6%	Materials and Coatings (> T <sub>3</sub> )
7FA.04	2010	57.8%	Hot gas path, single crystal blades
7FA.05	2012	57.9%	Compressor improvements

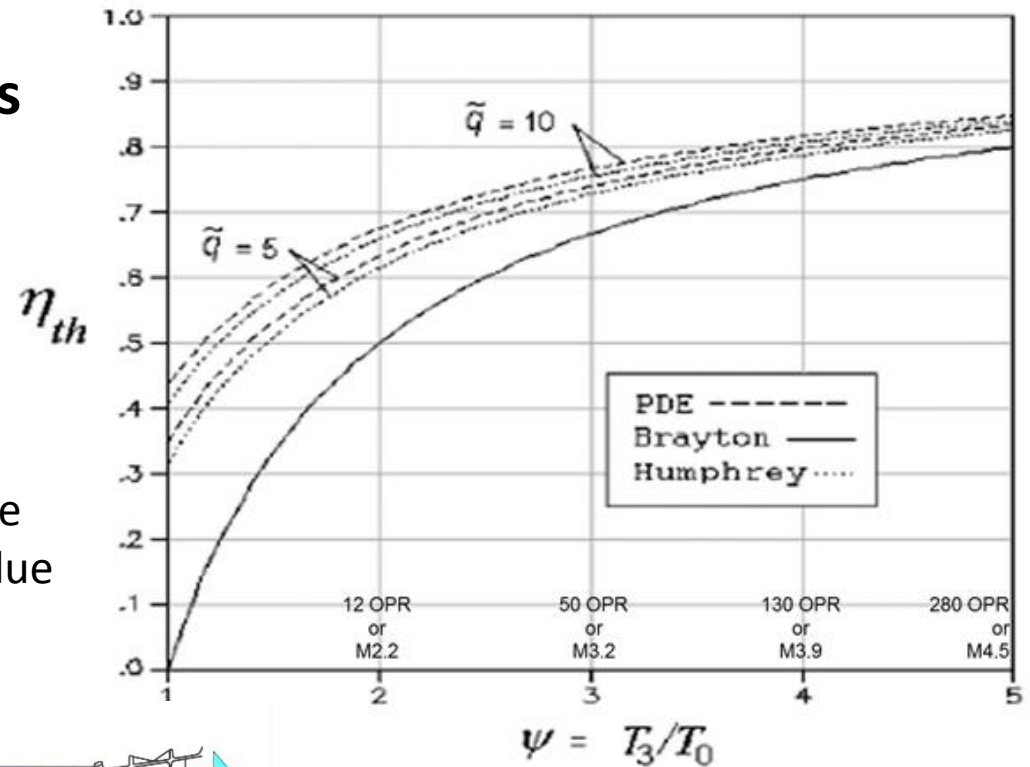

- The need for transformational technology!!
  - Combustion

# Constant Pressure vs Constant Volume Combustion

- **Convention gas turbines relies on Constant Pressure Combustion (Brayton cycle)**

- Utilizes Deflagration (slow combustion – subsonic)
- Actually results in a pressure loss across the combustor due to viscous effects

Constant volume combustion through detonation offers a pathway to improved efficiency compared to deflagration

Resonant Pulse Combustor (NASA-Glenn)

Wave Rotor Engine (IUPUI)

Multi-Tube PDE  
G.E. Global Research Center 2005

RDE Simulation  
Naval Research Laboratory - 2011

# RDC Potential Advantages

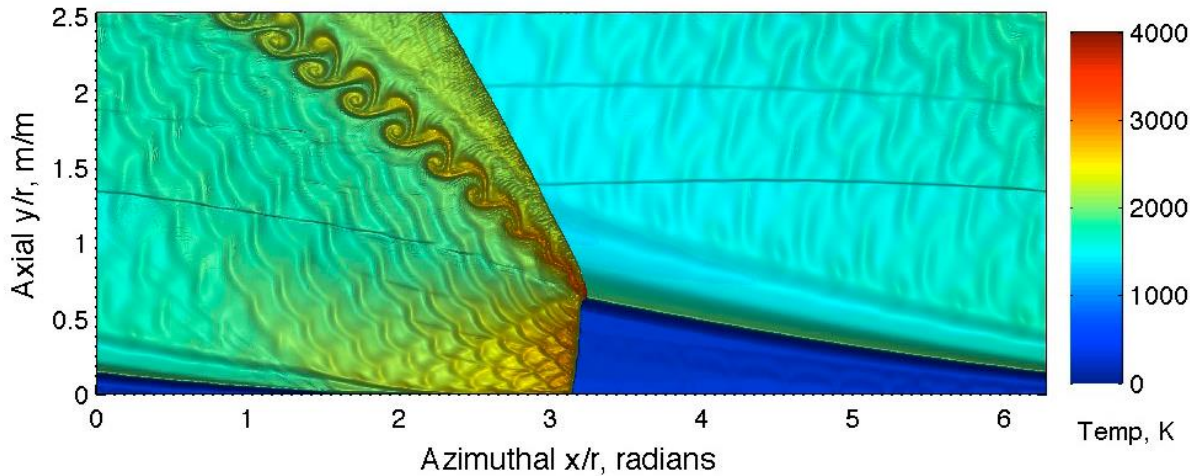

- Benefits are in addition to other gas turbine improvements
- Unlike related pressure gain combustion technology, RDE offer continuous flow eliminating the need to Purge and Fill events and complicated valving.
- Once initiated, detonation wave is self-sustaining (limited DDT)
- High frequency detonation results in quasi-steady flow through combustor exhaust.
- Scalable and good turn-down performance

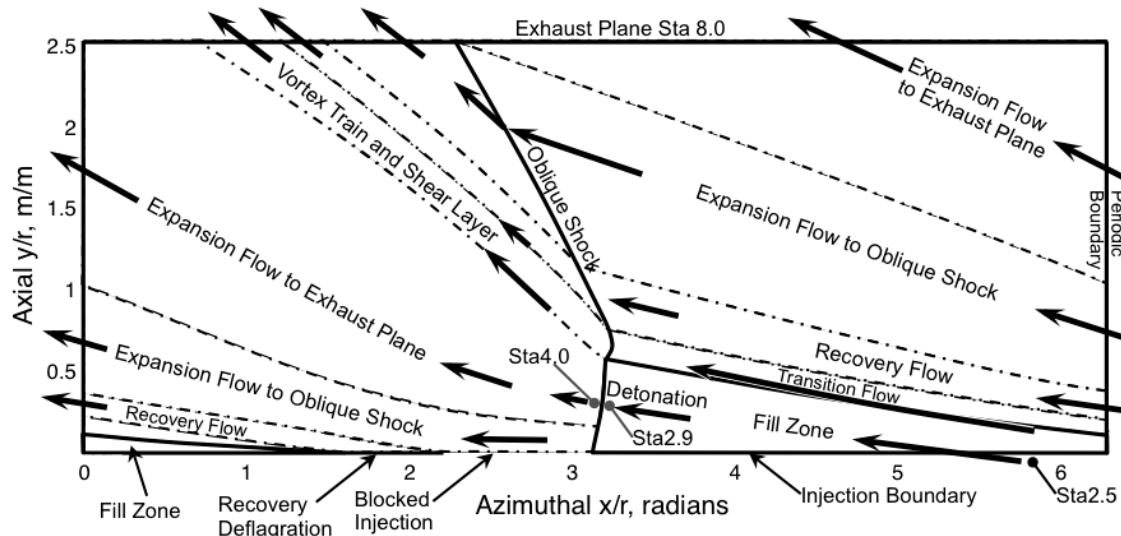

# Physical Characteristics of RDE Combustion

- Complex fluid and thermodynamic feature occur throughout the flow field (Nordeen, 2013)

Temperature with Density shading highlights complexity (Induction Parameter Model)

Different regions of the flow experiences different thermodynamic cycles

# Thermodynamic Analysis of RDE

- Individual streamlines exhibit unique thermodynamic cycles.

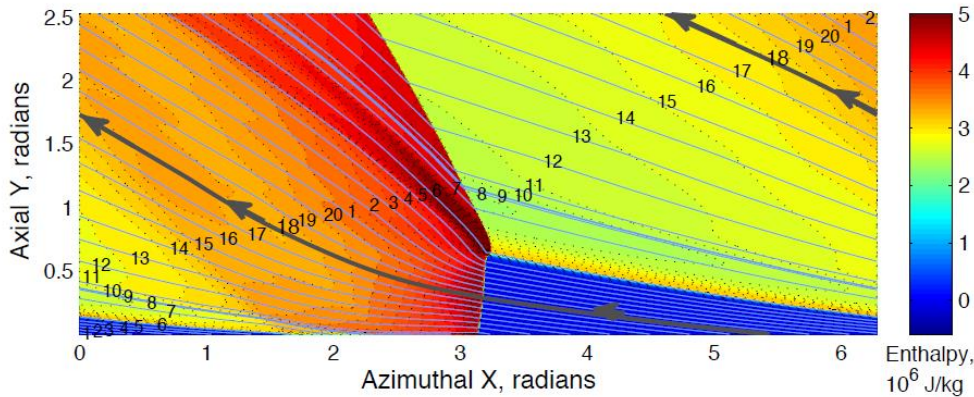

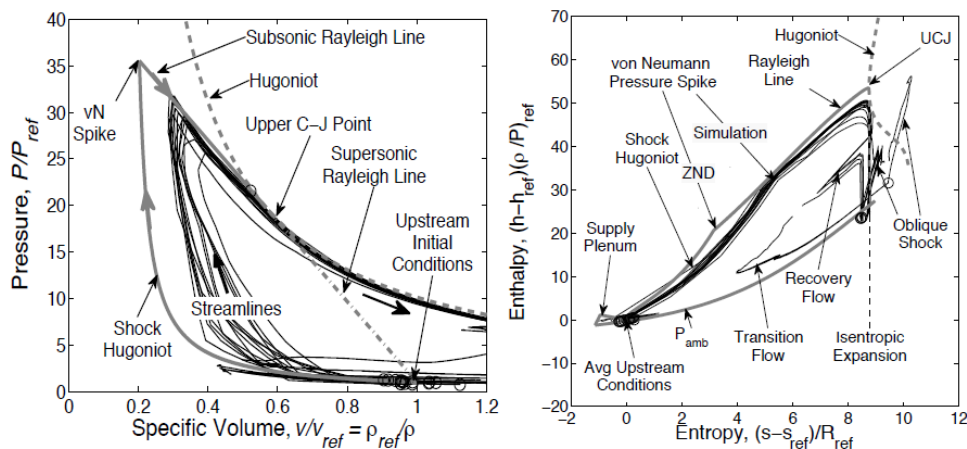

Figure 1-4 Time-averaged enthalpy with streamlines in rotating frame of reference [13]

One approach is to model flow along streamlines as individual thermodynamic cycles (Nordeen, 2013). But over-simplifies the chemistry.

PSR_Obq_2	2778.29	2.77829E+05	0.04614	

Reactor zone properties

Reactor wise product mass fraction comparison with CFD

# Rotating Detonation, Continuous Wave, Combustion offers a set of unique challenges

- Combustor
  - Inlet/Injector design
    - Low-loss injectors
  - Combustion stability / Efficiency
    - Mixing
    - Limiting deflagration
    - Wave bifurcation
    - Directionality
  - Exhaust Transition
    - Maintain pressure gain
    - Sub-Sonic vs Super-Sonic
  - Unsteady Heat transfer
  - Emissions
    - High or low NOx

# Rotating Detonation, Continuous Wave, Combustion offers a set of unique challenges

- Compressor (unsteady flow or backflow from combustor) – could this induce surge / stall on the compressor
- Turbine
  - Turbine blade film cooling with PGC
  - Integration of Combustor to Turbine to minimize pressure loss.
- Cycle benefit from pressure gain
  - Hybrid cycles
  - Coupled with reciprocating engine for turbo-compounding in a PDE arrangement taking advantage intermittent flow from cylinders.

# NETL-ORD Program Objectives

- Identify and address knowledge gaps relative to detonation and shock wave management for sustained combustion in land based power generation applications.
- Define a realistic pathway for implementing pressure gain combustion in a gas turbine engine for land based power generation.
- Provide experimental data for model validation

# NETL Bench-Scale Experimental Research

- **Hardware / Facilities**

- AFRL 6" RDE, H<sub>2</sub>-Air
- Facility capabilities
  - 30 bar (30 atm)
  - 800 K (1000 F) preheat
  - 2100 K (3100 F) combustion temperatures
  - 1.5 kg/sec (3.2lb/sec) combustion air
  - H<sub>2</sub>, NG, Propane, Ethane

- **Objectives**

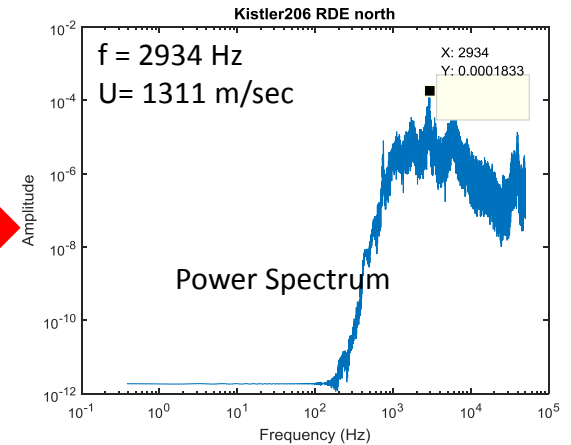

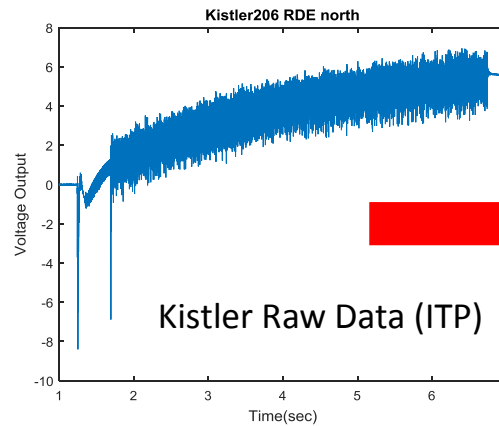

- Influence of pressure on RDE
- Low loss inlet and wave directionality
- Exhaust flow transition for turbine
- Heat transfer
- NO<sub>x</sub> Emissions
- Generate validation data for models

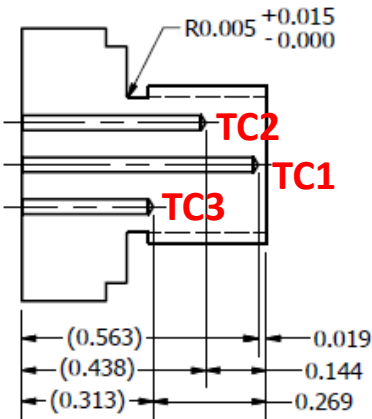

# Preliminary Data Analysis

- Dynamic Pressure measurements using fast response transducers in ITP (Infinite Tube Pressure) and flush mounted configuration

- Transient Heat Flux estimate

**Simplification: 1-D Semi-infinite Transient Conduction**

- Transient heat flux<sup>1,2</sup> @ x = 0

$$q(t_N) = 2\sqrt{\frac{\rho C k}{\pi}} \left[ \sum_{i=1}^N \frac{T_s^*(t_i) - T_s^*(t_{i-1})}{(t_N - t_i)^{1/2} - (t_N - t_{i-1})^{1/2}} \right]$$

q12 -> Heat flux using TC2-TC1

<sup>1</sup>Dennis E. Liliekis, AFRL, MS thesis, 1986

<sup>2</sup>Cook and Felderman, AIAA, 1966

# NETL RDE Inlet Experiments

- **Linear RDE apparatus designed and fabricated to facilitate development of improved inlets**
  - Inlet and plenum optically accessible from multiple sides
  - Detonation pressure wave created by accompanying H<sub>2</sub>/air detonation tube
  - 3D printed inlet geometries for rapid evaluation of designs
  
- **Scaling and similitude used to maintain relevance to full-scale, fired RDE at NETL MGN**

# Linear RDE Apparatus

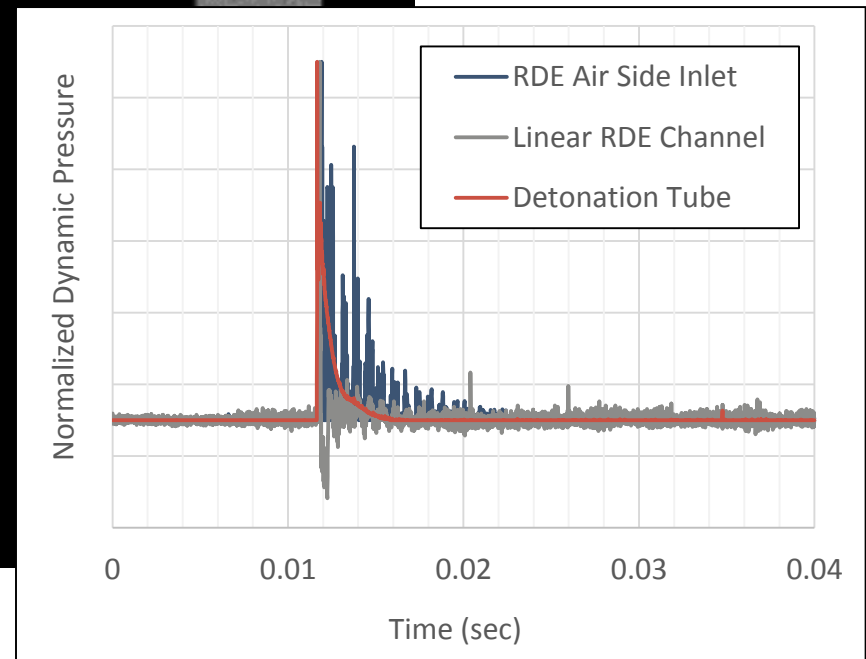

- **Non-reacting gases within inlet passages (He/air)**
  - H<sub>2</sub>/air detonation tube connected to end of linear RDE channel
  - 3D printed inlet geometry mimics RDE cross section at 1:1 scale
  - Optical accessibility permits non-intrusive data collection

- **Rapidly propagating pressure wave creates characteristic backflow and recovery behavior seen in full-scale, fired RDE**
  - Diagnostics include dynamic pressure measurements and high-speed Schlieren imaging to evaluate inlet dynamics, acetone PLIF for fuel/air mixing within channel

# Synchronized Measurements

# CFD Modeling of NETL RDE

- Fluent being used to simulate RDE operation.
  - 3D grid (~1.8M cells) includes discrete fuel injection and air slot with partial manifolding.
  - 1 step H<sub>2</sub>/Air mechanism, no combustion model.
  - k-ε turbulence model.
- Characterizing overall thermal efficiency, pressure gain/loss, potential turbine work, etc...

## Temperature Contours ( $\phi = 1.0$ )

**Simulation shows significant interface burning (~40% of fuel). Turbulence chemistry interaction models are not valid for both deflagration and detonation zones.**

- ***Includes Air and Fuel Injectors and Partial Manifolding***

# Modeling Upstream at the Inlet

*Temperature*

*H<sub>2</sub><sup>5</sup> Cold Flow*

- **Combustion gasses and shock waves propagate back into manifolding.**

# CFD Modeling of NETL RDE

Simulations to evaluate turbine integration, effect of pressurized operation (S. Escobar, I. Celik, West Virginia University).

Mach number contours for  $P_{out}=0.11\text{atm}$  (top) and  $P_{out}=2.0\text{atm}$  (bottom)

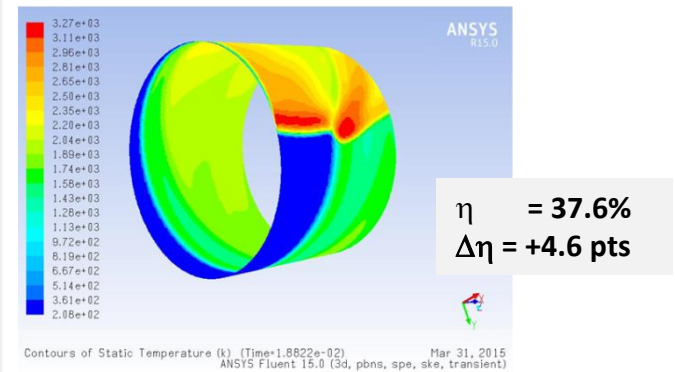

Schematic of simulation of interaction of RDE and integrated turbine exit.

Parametric study to define loss mechanisms

Baseline case, steady, premixed combustion at 6 bar:  $\eta = 33\%$

No inlet, premixed, no heat loss

With inlet, no heat loss

# DOE / NETL PGC Funded Activities

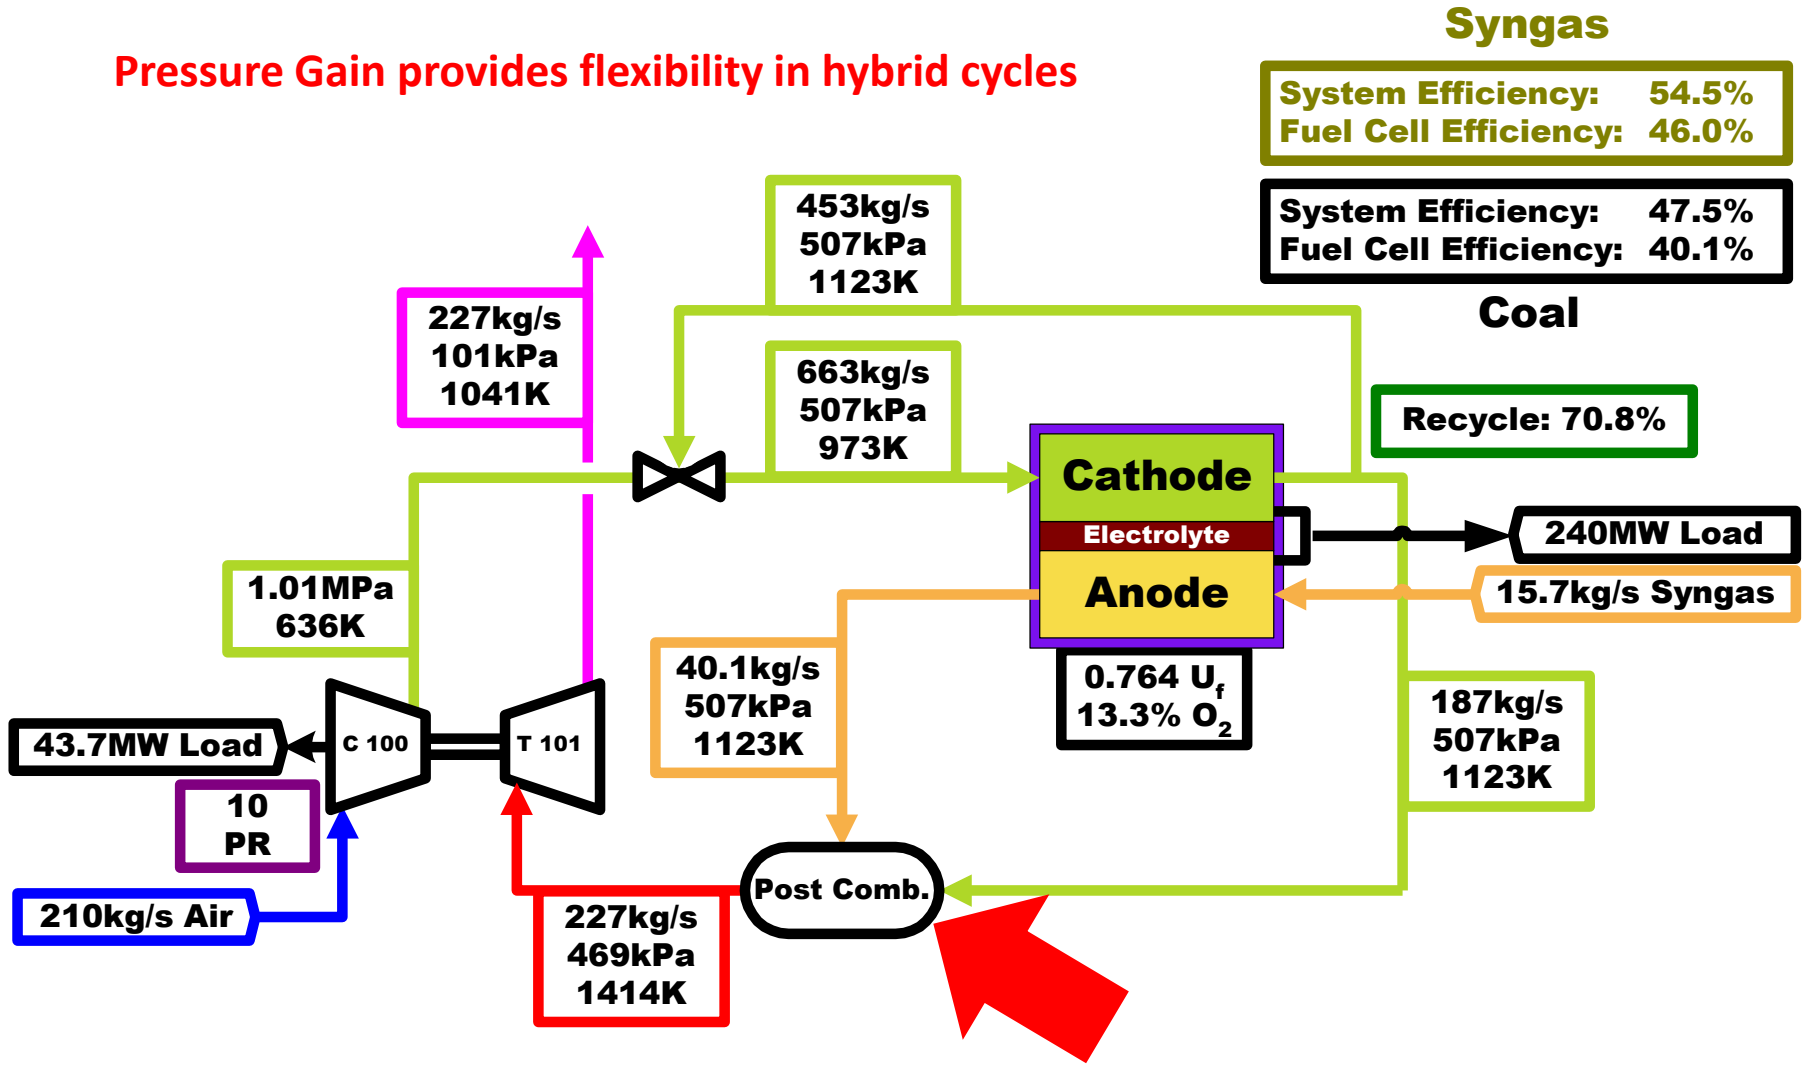

- **Aerojet Rocketdyne (FY15-16)**
  - Develop, validate, and integrate a systems model for a rotating detonation combustor into an overall systems model of a power plant and define the path to configurations that exceed 65 percent combined-cycle efficiency.
- **UTRC (FY15-16)**
  - Assess the potential benefit of PGC system technology for combined-cycle gas turbines and compare it to the DOE goals.
- **Penn State University (FY15-17) - UTSR**
  - Impact of fuel-oxidizer mixture concentration inhomogeneity on detonation wave quality and stability in a hydrogen and hydrogen/natural gas with air fueled RDE.
  - Parametric study to better understand relationship between combustor geometries and injector performance.

# DOE / NETL PGC Funded Activities

- **University of Michigan (FY15-17) - UTSR**
  - Explore fundamental physics governing non-idealities and impacted performance in a linear RDE analogue.
  - Develop detailed computational tools (DNS & LES) for studying detonation wave propagation processes in RDEs.
- **Purdue University (FY15-17) – UTSR**
  - Characterize the performance of RDE injection/mixing systems using an optically-accessible, linear platform with actual injector geometry.
  - Evaluate the operability of an RDE combustion chamber relative to installation in a gas turbine system
- **Oregon State University (FY15 – FY 17)**
  - Evaluate the performance of a Pulse Detonation Engine for an application in a MHD System.

# Cathode Recycle Configuration with Ejector

Pressure Gain provides flexibility in hybrid cycles

# Making Oxy-fuel an Advantage

## Direct Power Extraction (via MHD)

- **Magnetohydrodynamic (MHD) Power Generator:** Use a strong magnet and convert kinetic energy of conductive gases directly to electric power
- **Higher plant efficiency – works at higher temperature**
  - Need to use in combined cycle
  - Synergy w/ oxy-fuel for CCUS
    - oxy-coal COE much higher than baseline COE primarily due to ASU
    - Legacy: MHD-steam coal has ASU (to combust to higher T) but COE lower than baseline COE ->

**MHD cycle turns having an oxygen production from efficiency disadvantage to efficiency advantage!**

**A Turbogenerator**

**B MHD Generator**

# Questions??
