## The 21<sup>st</sup> Century Grand Challenge: Enabling Energy and Environmental Security By Solving the Carbon Problem

> Half of CO<sub>2</sub> emissions are from  
*small dispersed sources*  
(transportation, home, small industries)

### “Power” from 1m<sup>2</sup> of area @ 10 m/s

CO<sub>2</sub> in 1 m<sup>3</sup> of Air: 0.015 moles

In 1 year, at 370 ppm & 3 m/sec,  
the air moving through a 1 m<sup>2</sup>  
opening carries several times the  
**20 tons/capita for the US.**

0.66 g CO<sub>2</sub>/m<sup>3</sup>  
(x 3 m/s x 3.15 x 10<sup>7</sup> s/yr)

#### Extraction from Air

Raw Power Equivalent  
from gasoline  
v = 10 m/s  
100,000 W/m<sup>2</sup>

#### Fossil Energy Density is VERY High

At 370 ppm & 10 m/sec, the CO<sub>2</sub> in air  
moving through a 1 m<sup>2</sup> opening allows  
the generation of several hundred times  
the energy extracted by a 1 m<sup>2</sup> windmill.

Wind Energy  
v = 10 m/s  
600 W/m<sup>2</sup>

Sunshine  
200 W/m<sup>2</sup>

Biomass  
3 W/m<sup>2</sup>

## Order of Magnitude Cost Estimate ~ \$25 ton of CO<sub>2</sub>

CO<sub>2</sub> Collection Cost by Analogy to Wind Mills: ~ \$8/ton of CO<sub>2</sub>

- Windmills cost ~\$700/m<sup>2</sup> of swept area.
- 1 m<sup>2</sup> sweep area, 3 m/s velocity, 50% efficiency, 3.5 kg CO<sub>2</sub> / hour
- Annual loan, operation & maintenance costs ~ 30% of capital cost

CO<sub>2</sub> Calcination Costs by Analogy to Cement: ~ \$14/ ton of CO<sub>2</sub>

#### Another estimate of Calcination Costs

- At 100% efficiency 0.14 ton of coal needed per ton of CO<sub>2</sub>.
- At a price of \$20/t, 70% eff., coal costs are \$4 per ton of CO<sub>2</sub>
- Annualized cost of the coal power plant ~4 x fuel cost: **\$16**

## Issues to Address

- 1) Energy expenditure for pressurizing CO<sub>2</sub>
  - 20 kJ/mole minimum to P = 1 atm
- 2) Sorbent Issues
  - Recycling penalty
  - Selectivity
  - Handling
- 3) Minimization of active extraction area
  - Optimal unit size
  - Air remixing
  - Downwind low CO<sub>2</sub> concentrations
- 4) Predictable/efficient air flow
  - Wind vs. forced air flow
    - Energy requirements
    - Fraction of air/CO<sub>2</sub> intercepted
  - Minimizing system size
  - Maximizing CO<sub>2</sub> removal
  - Overall optimization
- 5) Makeup supplies
  - Water
  - Sorbent

60 m x 50 m Unit, 3 kg CO<sub>2</sub>/sec  
 Inefficiencies included  
 90,000 tons/year  
 15,000 cars equivalent  
 60,000 units for all of US CO<sub>2</sub>  
 250,000 units for global emissions

## Experimental Work

### Measurements of CO<sub>2</sub> Uptake from ambient Los Alamos Air

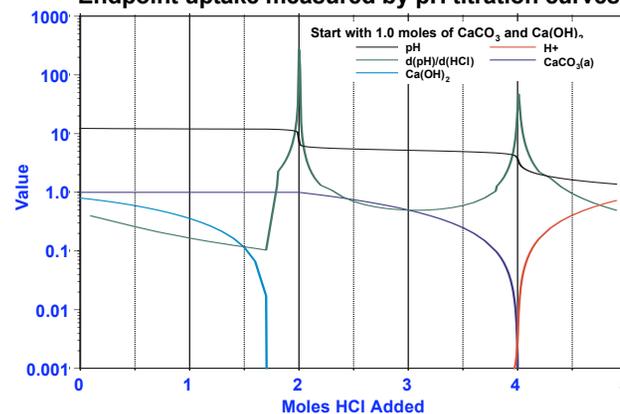

#### ACTIVE

Air passed thru adsorbent @ 750 ml/min  
 CO<sub>2</sub> measured continuously before & after  
 by non-dispersive IR absorption (LICOR),  
 And at the end point by pH titration

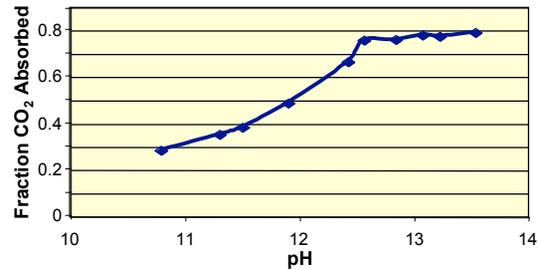

#### PASSIVE

Room air drawn into fume hood  
 interacts with alkaline solution.  
 pH titration of small aliquots yield  
 CO<sub>2</sub> uptake as a function of time.

### Endpoint uptake measured by pH titration curves

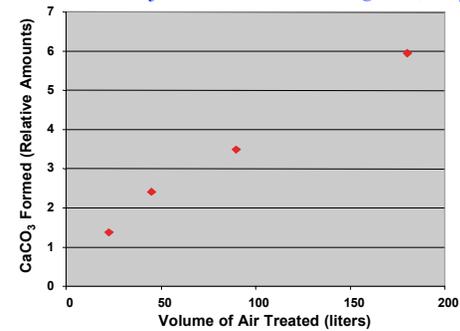

### pH dependence for CO<sub>2</sub> uptake from air bubbled through NaOH Solutions

Need pH > 10 or a catalyst at low pH.

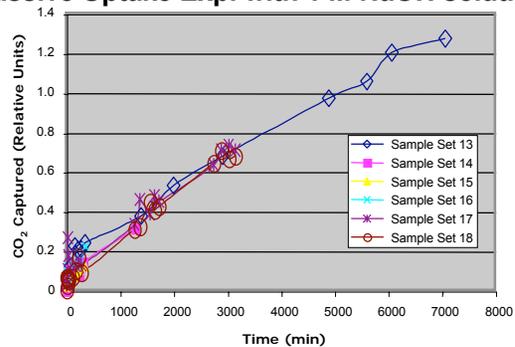

### Active Uptake Exps.: LICOR CO<sub>2</sub> & pH titration

CO<sub>2</sub> extracted as CaCO<sub>3</sub> from air bubbled through Ca(OH)<sub>2</sub> solution

LICOR CO<sub>2</sub> & pH titration agree; Collection increases ~ linearly with time  
Collection eff. = 53±5% (non-fritted impinger); > 70% (fritted impinger)

### Passive Uptake Exp. with 1 M NaOH solution

Observed Uptake ~ Ton C / m<sup>2</sup>·yr. Slow flow, air mixing in the fume hood.  
Mixing of liquid maintains alkalinity at surface.

### Design ideal CO<sub>2</sub> adsorbent for air capture

- Fast kinetics but weak binding
- High selectivity for CO<sub>2</sub> over H<sub>2</sub>O
- Nonvolatile and environmentally benign
- Aqueous, porous/coated solids, active membranes
- Large supplies, cost effective, and recyclable
- Target candidate scrubbers
  - Ca(OH)<sub>2</sub>, Mg(OH)<sub>2</sub> with promoters
  - Solid amines and ionic liquids
  - Zeolites, biomimics, membranes, carbon
  - Temperature, electric, pressure swing

### Competitive adsorbents to save energy for CO<sub>2</sub> recovery after capture

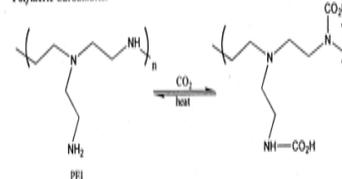

CO <sub>2</sub> Adsorbents	ΔH (CO <sub>2</sub> ) kJ/mole	ΔH(H <sub>2</sub> O) kJ/mole	T(CO <sub>2</sub> ) Recovery	Energy Penalty (Coal) Dry!
Ca(OH) <sub>2</sub>	179	-	~900	36%
Prim. Amine	84	47	~300	17%
Sec. Amine	72	47	~250	14%
Ter. Amine	48	47	~200	10%
Polyamine	94	47	350	19%
Ionic Liquids	Low	?	80-100	<10%

Entropic limit for CO<sub>2</sub>: 370 ppm to 1 bar is 20 kJ/mole-°C  
 [RT ln (P/P<sub>0</sub>); RT ~ 2.5 kJ/mole]

### High technology CO<sub>2</sub> adsorbents for open air: Recent Breakthroughs

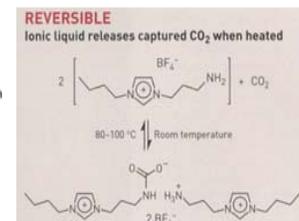

#### Polyethyleneimine

Polymeric Carbamates:

Used to stabilize CO<sub>2</sub> in space shuttle using pressure swing adsorption-desorption.

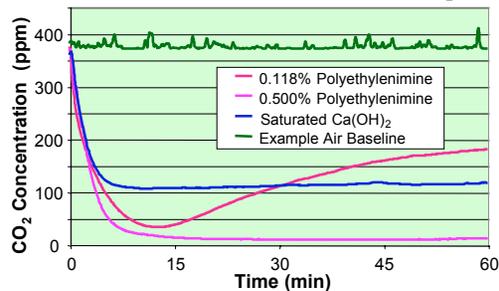

#### Ionic Liquid Imidazolium Salt

Rapid uptake & weak binding (~80 °C) reversal temperature

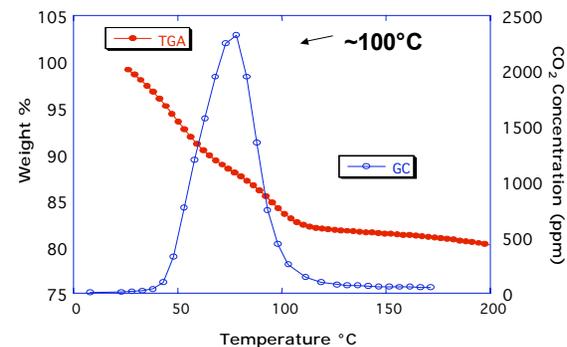

Viscous with low vapor pressure

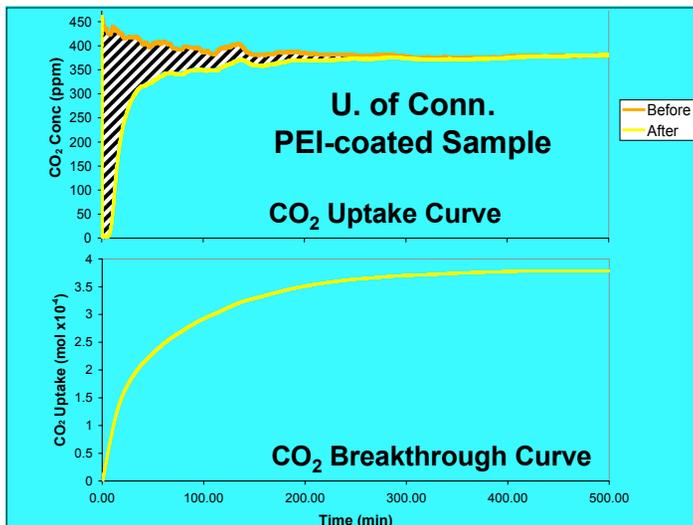

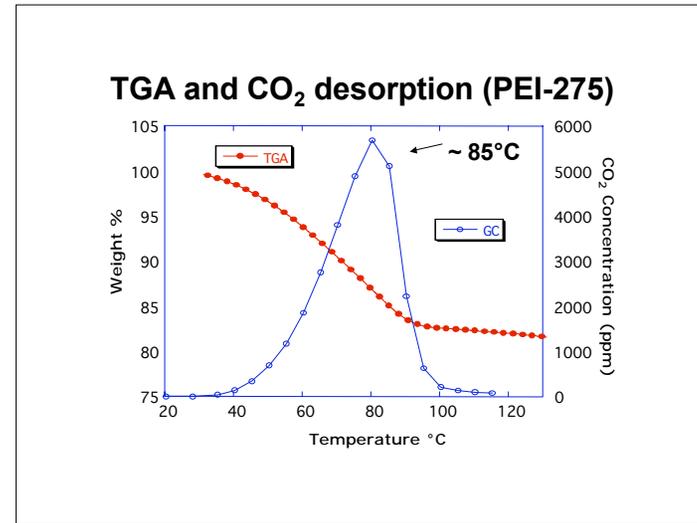

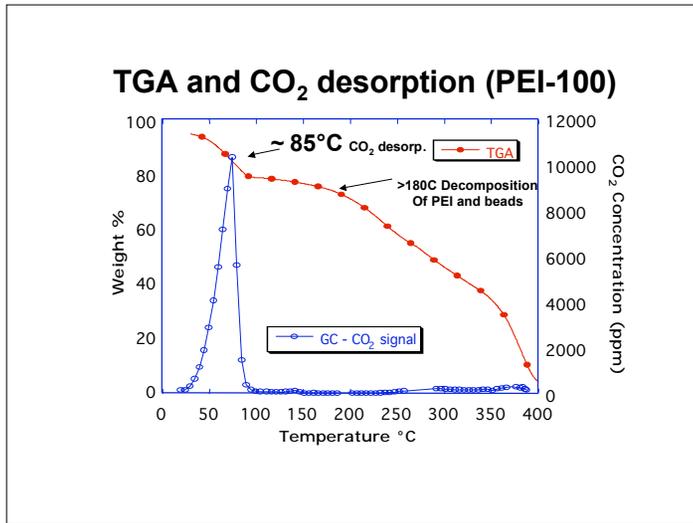

CO<sub>2</sub> uptake by Solutions in a Fritted Impinger: Polyethyleneimine (PEI) vs Ca(OH)<sub>2</sub>

PEI has good uptake kinetics & thermodynamics for CO<sub>2</sub> recovery, low vapor pressure and can be coated on high surface area solids, BUT solid polyamines will take up water as well!

### TGA and CO<sub>2</sub> desorption (XPEI)

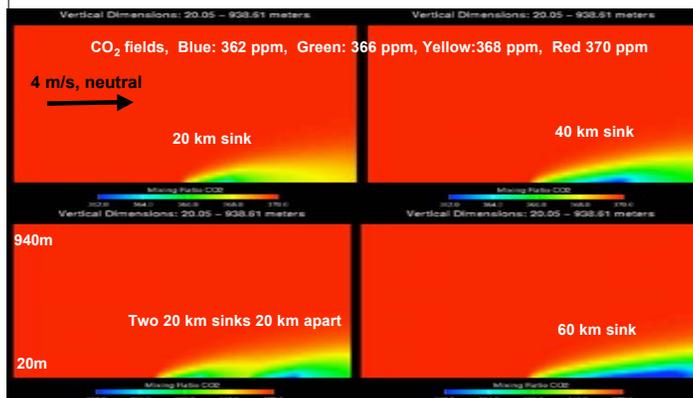

- ### Solid Polyethylinimine (PEI) Results
- **PEI coated beads (UConn) Sorbent**
    - Modified for T-swing adsorption process
    - Capacity: 0.08-0.15 g CO<sub>2</sub>/g-sorbent
    - Scales with surface area: 0.06g CO<sub>2</sub>/g-sorbent
    - Water uptake 0.1-0.5 g H<sub>2</sub>O/g-sorbent
    - Regeneration temperature: 85°C
  - **Cross-linked polyethylenimine (XPEI)**
    - Lower hydrophilicity (insoluble)
    - Capacity: 0.1-0.5 g CO<sub>2</sub>/g XPEI
    - Water uptake 0.1-0.3 g H<sub>2</sub>O/g-sorbent
    - Regeneration temperature: 100°C

## Ongoing and Future Work

- Examine more *solid amines* for CO<sub>2</sub> capture in dry air.
- Construct/operate 1 m<sup>2</sup> unit.
- Continue study of collector unit design.
- High resolution dispersion modeling to optimize the geometry, configuration, and nature of collection units.
- Examine participation in possible pilot project by Kelly Wright & Assoc., Tucson, AZ.

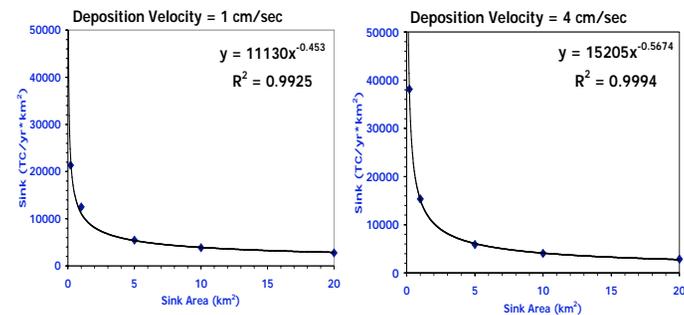

## Design Topics

### High resolution CFD modeling of CO<sub>2</sub> sink: Size dependence Shadow effects & vertical mixing to re-supply CO<sub>2</sub> to the surface

### CO<sub>2</sub> uptake flux as a function of sink size

Due to shadow effects, flux is higher for smaller sinks  
Models numerically validates anticipated L<sup>1/2</sup> scaling.

### Extraction: Natural Air Flow (~25%)

- CO<sub>2</sub> removal equivalent to momentum removal
- For 50% CO<sub>2</sub> removal, drop air velocity in 1/2
- 1/2 the surrounding velocity \* 1/2 the CO<sub>2</sub> in air
- Gives 1/4 of CO<sub>2</sub> in surrounding external air flow

### Energy for Moving Air: (Insignificant)

- CO<sub>2</sub> 370 ppm = 0.015 moles CO<sub>2</sub>/m<sup>3</sup> air
- Air: 66.67 m<sup>3</sup> = 1 mole CO<sub>2</sub>, ρ<sub>air</sub> = 1.225 kg/m<sup>3</sup> air
- 1 mole CO<sub>2</sub> = 82 kg air
- CO<sub>2</sub> removal equivalent to momentum removal
- For 100% CO<sub>2</sub> removal effectively stop air
- Accelerate air from stop to v, stop it, reaccelerate it
- Total energy added = 2 \* 1/2 mv<sup>2</sup> = mv<sup>2</sup>
- v = 3 m/sec: Energy to move air for 1 mole CO<sub>2</sub> = 735 J
- Gasoline ~ 650,000 J/mole C

### Absorber: Wet vs. Dry

#### WET

- + Liquids easy to move
- + Precipitates easy to collect
- Lots of dead mass
- Evaporation (Loss of water)
- Deposits / Scaling

#### DRY

- + Likely lower calcination energy
- Solids handling / Calcination
- Diffusion into solids
- Active solid mass handling
- Water Absorption into sorbent

### Scales: Capturing the CO<sub>2</sub>

- Molecular diff. coef. of CO<sub>2</sub> in air:  $D = 1.39 \times 10^{-5} \text{ m}^2/\text{s}$
  - Mass flux to absorbing surface:  $N = D \text{ grad } \rho = D \rho_{\text{CO}_2} / d$
  - $d$  is the transport distance (normal distance to wall)
  - $\rho_{\text{CO}_2} = 370 \text{ ppm} * 1.225 \text{ kg/m}^3 * (44/29)$  (perfect absorber)
  - Have box: height:  $h$ ; length:  $L = vt$ ; 1/2 width:  $d$  (center-wall)
  - $v$  = air speed,  $t$  = time to remove all CO<sub>2</sub> from box
  - CO<sub>2</sub> mass in box =  $Vol * \rho_{\text{CO}_2} = hL2d\rho_{\text{CO}_2} = hvt2d\rho_{\text{CO}_2}$
  - Mass flow to 2 walls =  $hL2N = hvt2N = hvt2D \rho_{\text{CO}_2} / d$
  - By box end the 2 are equal:  $d^2 = Dt$  or  $L = vd^2/D$
  - For  $v = 3 \text{ m/s}$ ,  $d = 2 \text{ mm}$  (4 mm absorber spacing);  $L = 86 \text{ cm}$
  - For  $v = 3 \text{ m/s}$ ,  $d = 1 \text{ mm}$  (2 mm absorber spacing);  $L = 21 \text{ cm}$
- System can be quite short**
