Data Analytics for Designing Fe-9Cr Steels Vyacheslav N. Romanov and Jeffrey A. Hawk, NETL J. Carter, R. French, L. Bruckman, and A. Verma, CASE WESTERN RESERVE UNIVERSITY Advanced Alloy Development FWP, Task4: Materials Data Analytics; PI: V. N. Romanov, Ph.D.

INTRODUCTION and APPROACH

Motivation for this research comes from the desire to shorten the rigorous and time-consuming alloy qualification process. The main consideration for using martensitic-ferritic steels is relatively high microstructural stability at the operating temperature over time, since power plants have a design lifetime of over 30 years. A materials data analytics methodology was developed to evaluate publicly available information on 9% Cr family steel and to handle nonlinear relationships and the sparsity in materials data for this alloy class.¹ Data entries for over 90 unique compositions, processing parameters, and results of tensile mechanical tests used in this study were arranged in 47 columns by 3000 rows.²

- ✓ NETL developed alloy database and used it to interrogate mechanical properties of Fe-9Cr steels
- \checkmark Partitioning revealed the biased nature of alloy datasets, multicollinearity due to conventional design practices.¹

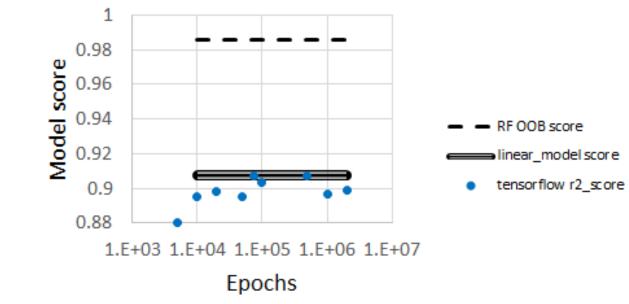

Exploratory analysis: scatter plots and a heatmap of Pearson correlations

 \checkmark Generic algorithms are not transparent:

- Tempering and test temperature effects on the mechanical properties were identified as major contributors (accounting for >80% of the data variation) and modeled first, before searching for minor effects of the composition variations.
- Ensemble models outperformed benchmark (NumPy & TensorFlow) linear optimization models. Model selection

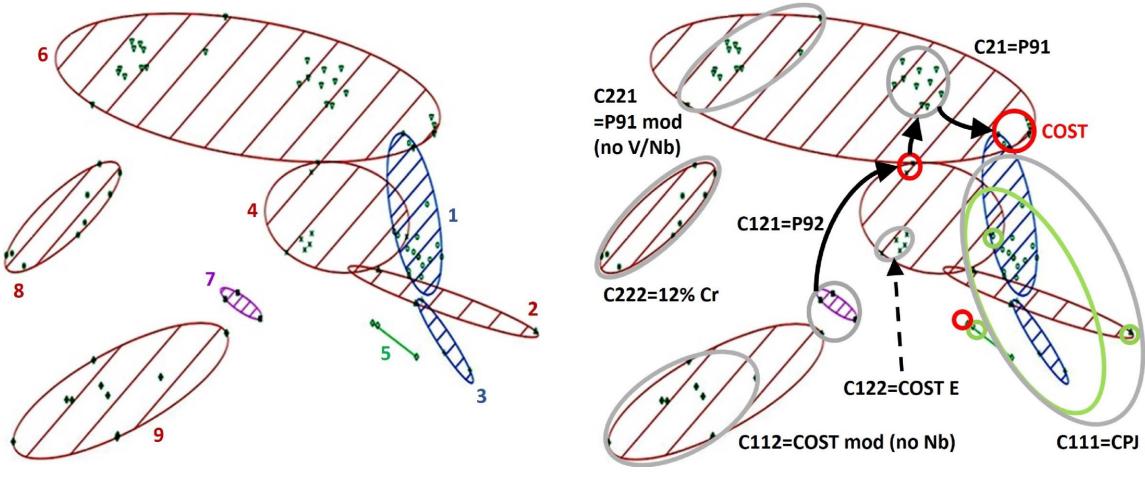

- \checkmark Validated ensemble models demonstrated high predictive power; >98% of the tensile strength variation was explained (93% of the design contributors vs 50% for the benchmarks).
- New alloy designs were explored. C and Mn were identified¹ as global contributors to tensile strength. Among cluster-dependent contributors, Cr, V, N, Si, Ni, and Nb were most consistently identified as major.³ In ensemble modeling, non-linear behavior associated with Mo, W, Co, and Cu is manifested as critical as well.

✓ New¹ algorithm: clustering for Information Gain (c-IG) without prior dimensionality reduction matched industry classification (Left: PAM)

- ✓ New¹ algorithm: Chebyshev metric adopted to modify k-NN using c-IG pre-seeded centroids:
 - $\|\mathbf{z}\|_{p} = (\sum_{i=1}^{n} |z_{i}|^{p})^{1/p}$, for $p \in \mathbb{N}$ (natural number, $1 \le p < \infty$)

ACKNOWLEDGEMENTS

This work was performed in support of the US Department of Energy's Fossil Energy Crosscutting Technology Research Program, Briggs White NETL Technology Manager, and Regis Conrad DOE-FE HQ Program Manager. The research was executed through the NETL Research and Innovation Center's Advanced Alloy Development Field Work Proposal. Research performed by an appointment to the Internship/Research Participation Program at NETL, administered by ORISE. CWRU research was funded under the DOE contract DE-FE0028685 with NETL.

✓ 29 public releases (papers and conference presentations)

BENEFITS AND FUTURE WORK

The project produced a methodology to guide the DOE-wide effort on materials data analytics for extreme environments. The data-driven models without dimensionality reduction provide a transparent link to the domain knowledge base. The primary data gaps identified as related to missing information on detailed microstructure will be addressed in future work.
