RARE EARTH ELEMENTS (REEs) — chemical elements/metals found in the Earth’s crust—are integral to the way we live our everyday lives, from energy to technology to national security. They are used in transportation, health care, and national defense technologies, as well as things you use daily—like your computer hard drive and smart phone.

THE NEED TO IMPORT REEs MAY CHANGE
Thanks to our nation’s coal resources, the U.S. Department of Energy’s Office of Fossil Energy is focusing on developing technologies that can help recover REEs from coal and coal by-products, making it possible to recover REEs in a way that’s economical and environmentally friendly.

DEVELOPING REEs IN THE UNITED STATES MEAN MORE JOBS
In fact, a 2014 American Chemistry Council report said that earth elements could support more than $130 billion of economic output and provide associated jobs to more than 200,000 people in North America.

DEVELOPING A SUSTAINABLE, DOMESTIC REE SUPPLY
From coal and coal by-products could help the United States integrate Coal Country—attracting advanced manufacturing facilities and jobs to these areas.

From improving everyday technologies, to securing our energy independence, to creating jobs—there are plenty of advantages to developing an REE supply from U.S. coal and coal by-products. And the U.S. Department of Energy is working to make that happen.

THE DEMAND FOR REEs IS VERY HIGH
And it’s expected to grow. But they’re most commonly found in ores, or minerals, that are hard to break down and expensive to extract. That’s why the United States depends heavily on imports for needed REEs.

Currently, China is the leading provider of REEs—controlling over 90 percent of the world’s supply. Concerns that China may fail to supply the needed materials may be sparking a shift to develop REEs in the United States.
