- Technical background

- Technical approach

- Next steps

In 2013, 50% of new power generation capability came from natural gas, which was used in gas turbine power plants

These additions were split between “peaking plants” and combined cycle plants, both of which use gas turbines

Source: eia.gov

Objective of the program is to *understand, quantify, and predict* combustion instability during *transient operation*

---

- Two major deliverables for the program:
  1. Fundamental understanding of flow and flame behavior during combustion transients and mechanisms for transition to instability
  2. Development of a stability prediction or quantification framework

Objective of the program will be achieved through experimental study and close ties with industry

---

- Experimental program that includes two separate, complementary facilities
- Development of quantification and prediction frameworks will aid in applying the results from this work to other facilities, including industrial hardware
- Cost-share and partnership from GE Global Research will provide industry feedback and internship opportunities for students on project

# Overview of presentation

---

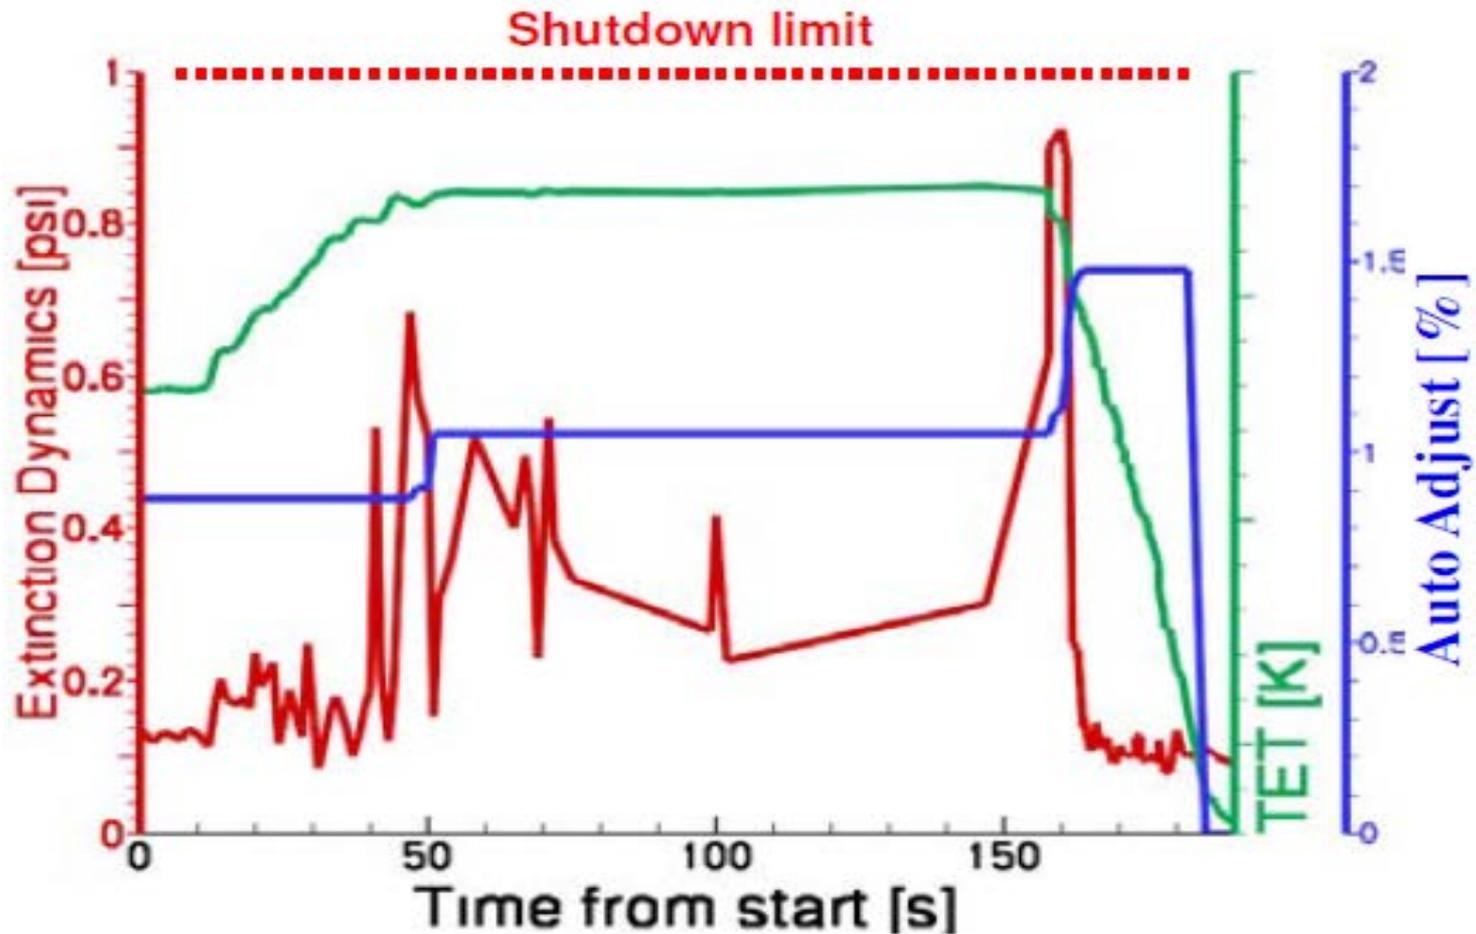

- Project motivation and objective

- Technical background

- Technical approach

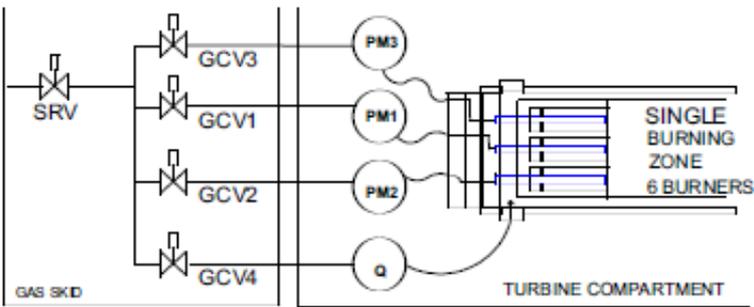

- Next steps

Very few studies have discussed the onset or control of instabilities during transient operation, but it's a common issue

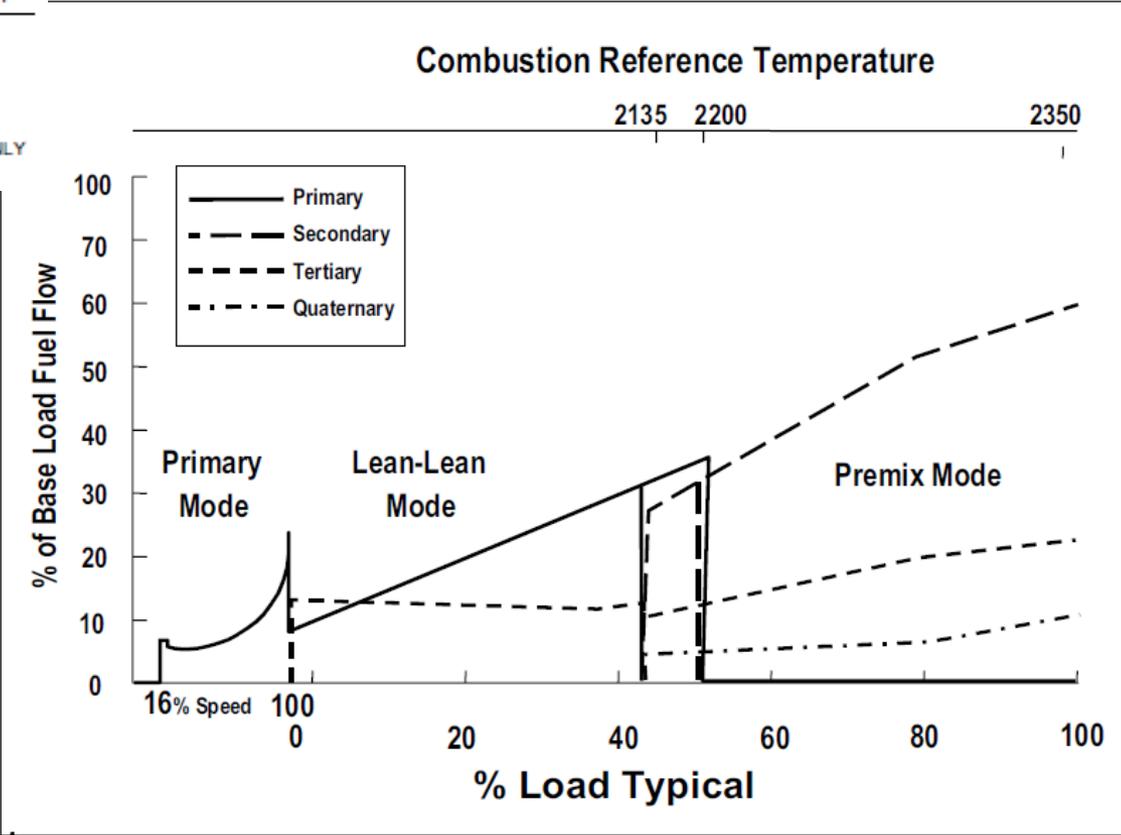

Transient operation of a Siemens SGT-200 (Bulat *et al.* 2007)

# Engine load is typically varied by either varying fuel staging or the equivalence ratio of certain fuel nozzles

SRV SPEED/RATIO VALVE  
 GCV1 GAS CONTROL PM1  
 GCV2 GAS CONTROL PM2  
 GCV3 GAS CONTROL PM3  
 GCV4 GAS CONTROL Quaternary

PM3 - 3 NOZ. PRE-MIX ONLY  
 PM2 - 2 NOZ. PRE-MIX ONLY  
 PM1 - 1 NOZ. PRE-MIX ONLY  
 Q - QUAT MANIFOLD, CASING, PRE-MIX ONLY

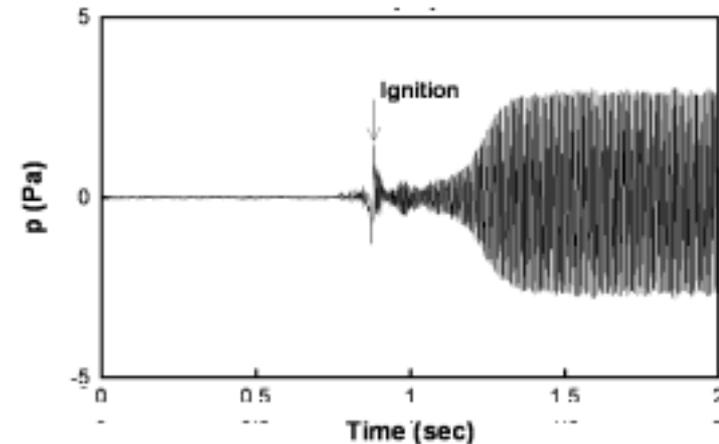

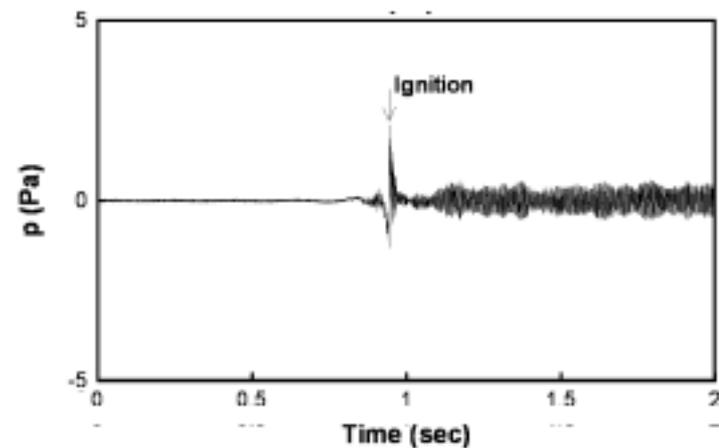

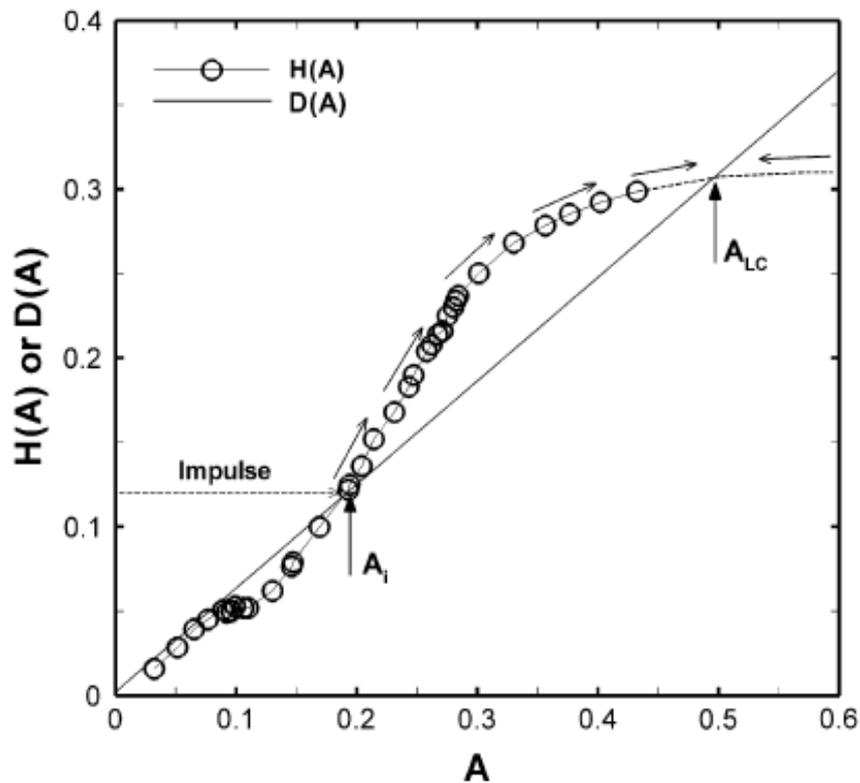

Source: Davis and Black, "Dry Low NO<sub>x</sub> Combustion Systems for GE Heavy-Duty Gas Turbines"

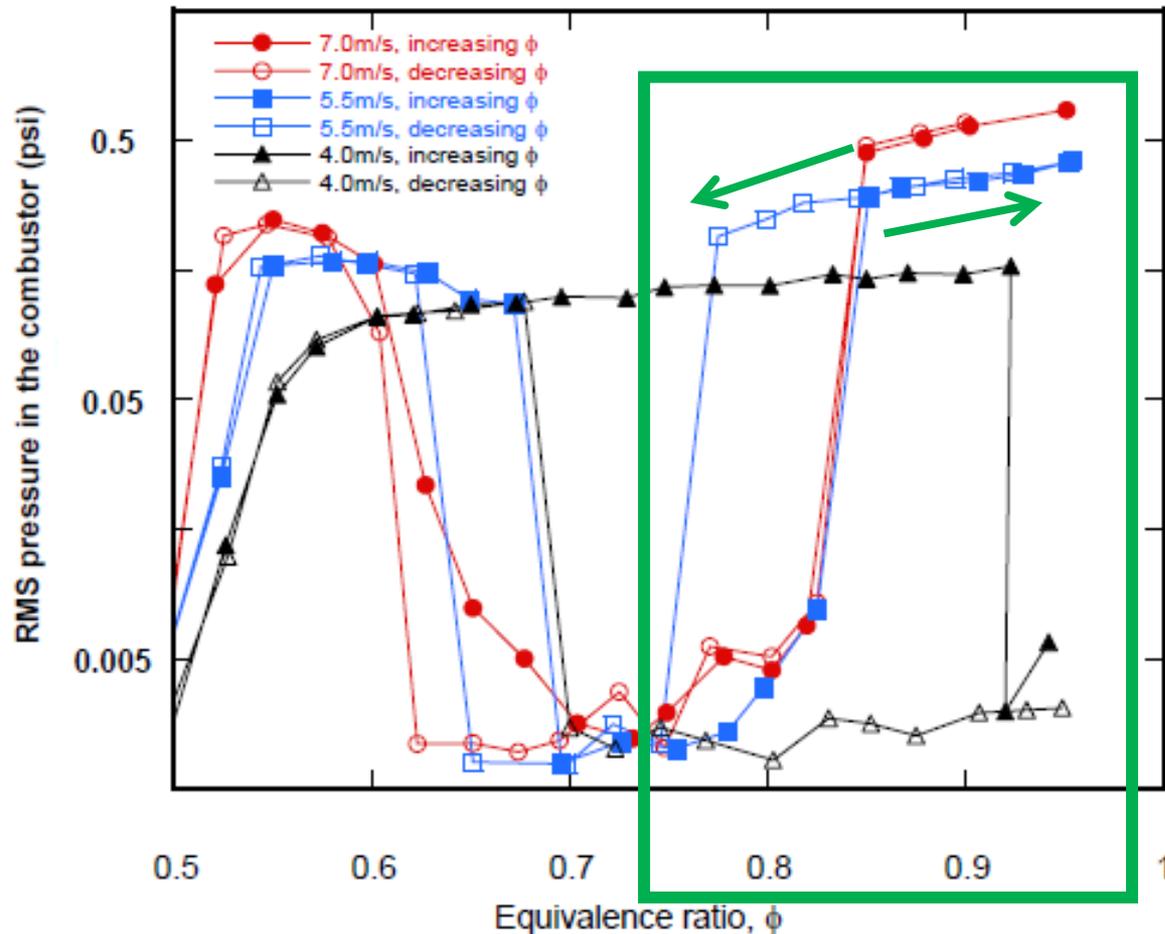

Most of the focus on transient operation has been on hysteretic or triggering behavior in combustion systems

---

Most of the focus on transient operation has been on hysteretic or triggering behavior in combustion systems

Most of the focus on transient operation has been on *hysteretic* or triggering behavior in combustion systems

Instabilities may arise as a result of changes in flame shape and flame anchoring that occur with variation in equivalence ratio

Photographs of multi-nozzle flame at  $U = 25$  m/s,  $T_{in} = 200^\circ\text{C}$

$U = 22.5 \text{ m/s}$ ,  $T_{\text{in}} = 200^\circ\text{C}$ , fully premixed, unforced

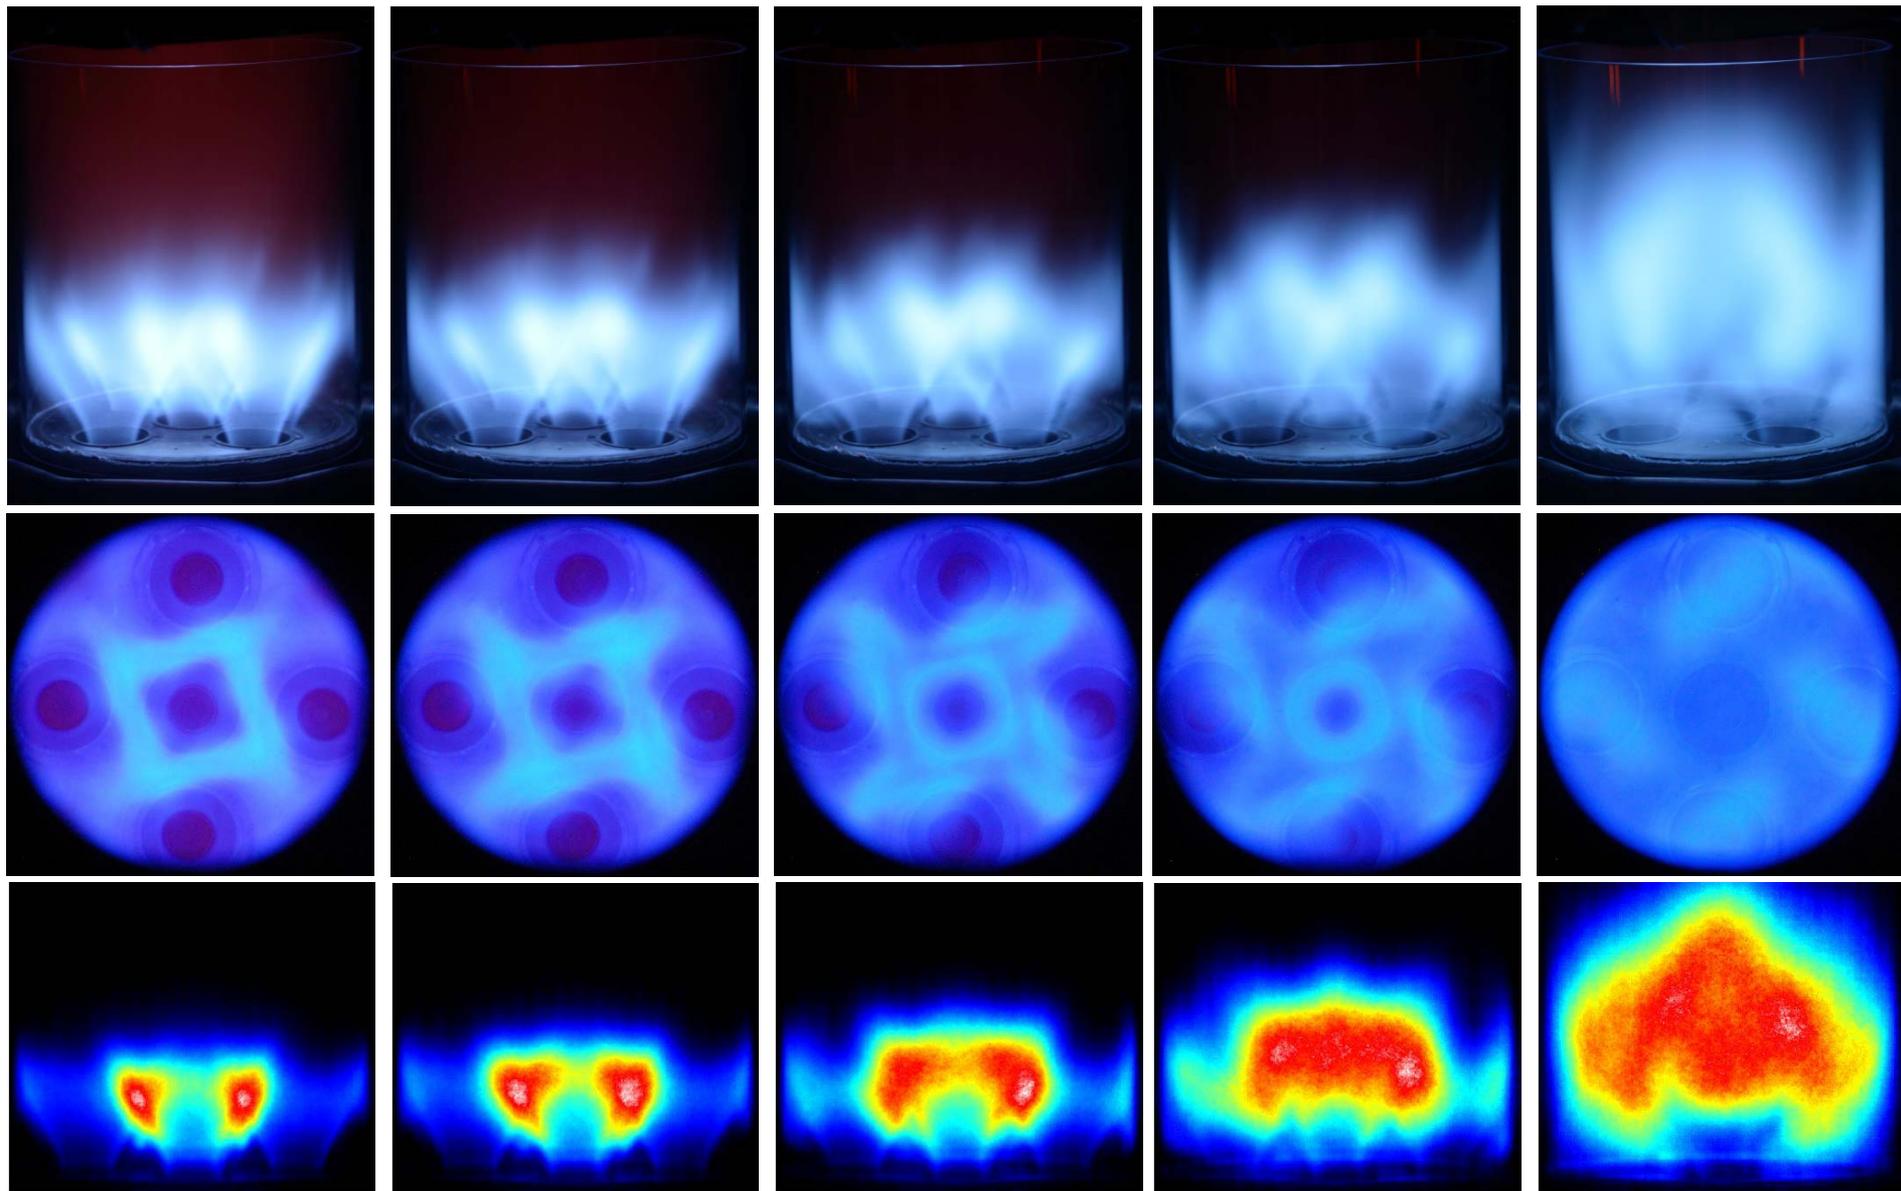

$\varphi = 0.65$

$\varphi = 0.60$

$\varphi = 0.55$

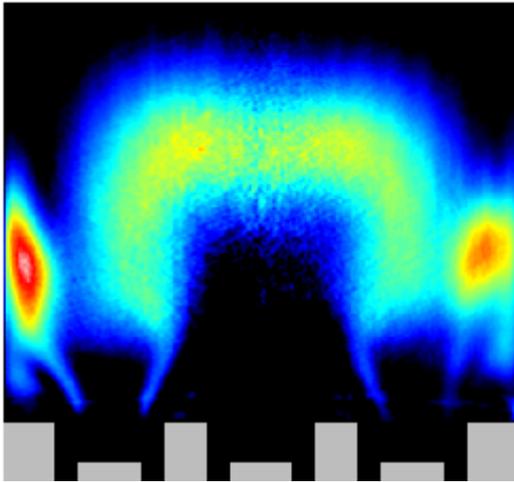

$\varphi = 0.50$

$\varphi = 0.45$

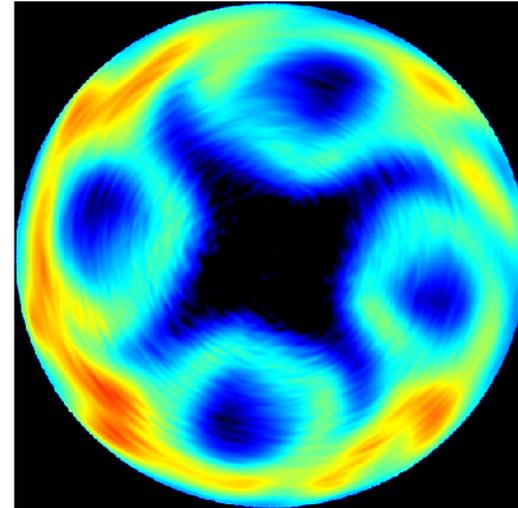

To further investigate the structure of the multi-nozzle flame, 3-D image sets were obtained at  $\phi = 0.60$  and  $\phi = 0.48$

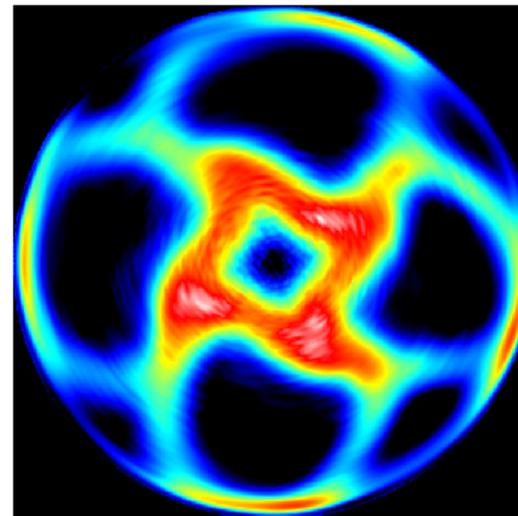

$\phi = 0.48$

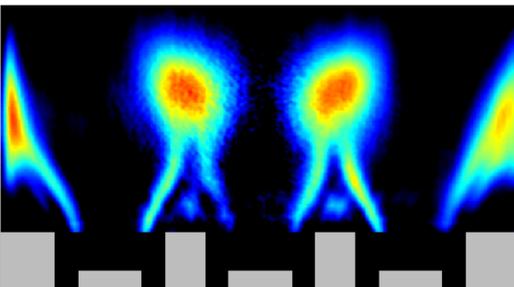

$\phi = 0.48$

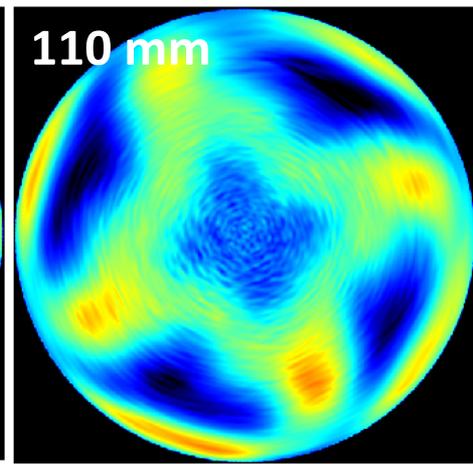

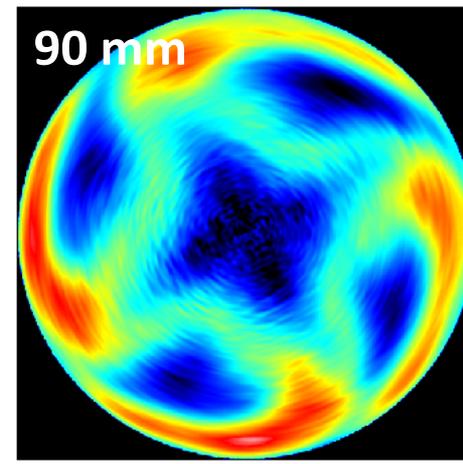

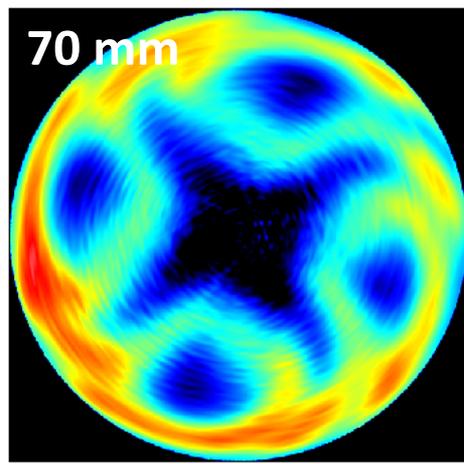

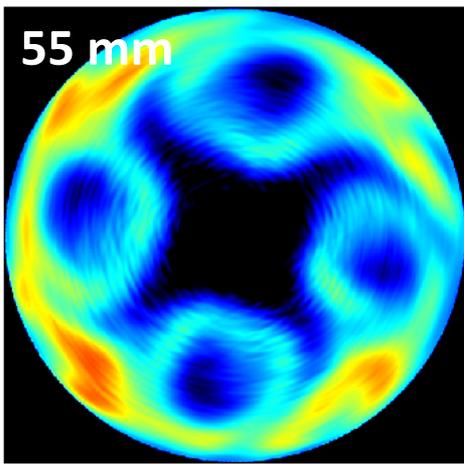

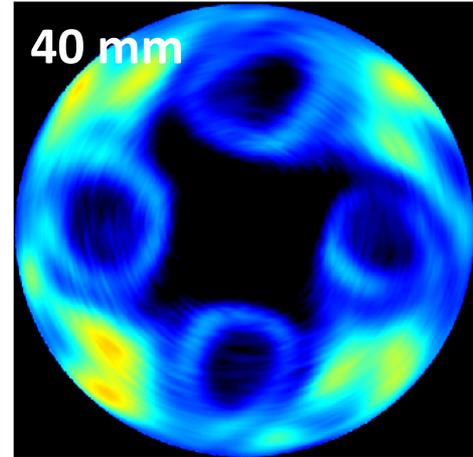

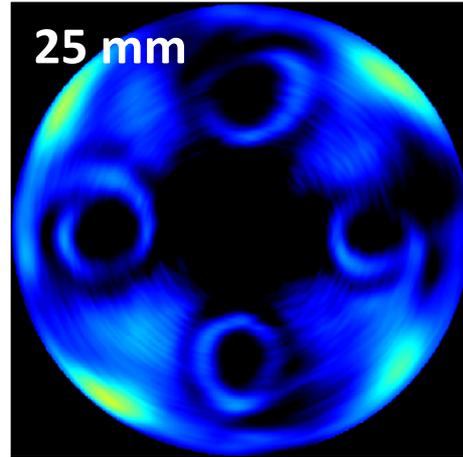

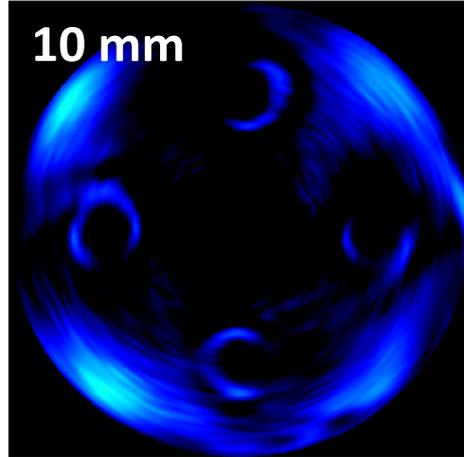

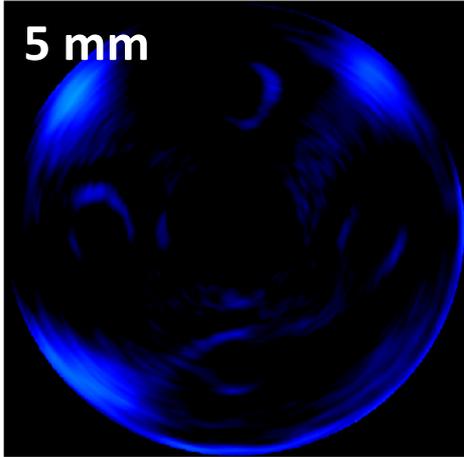

$\phi = 0.60$

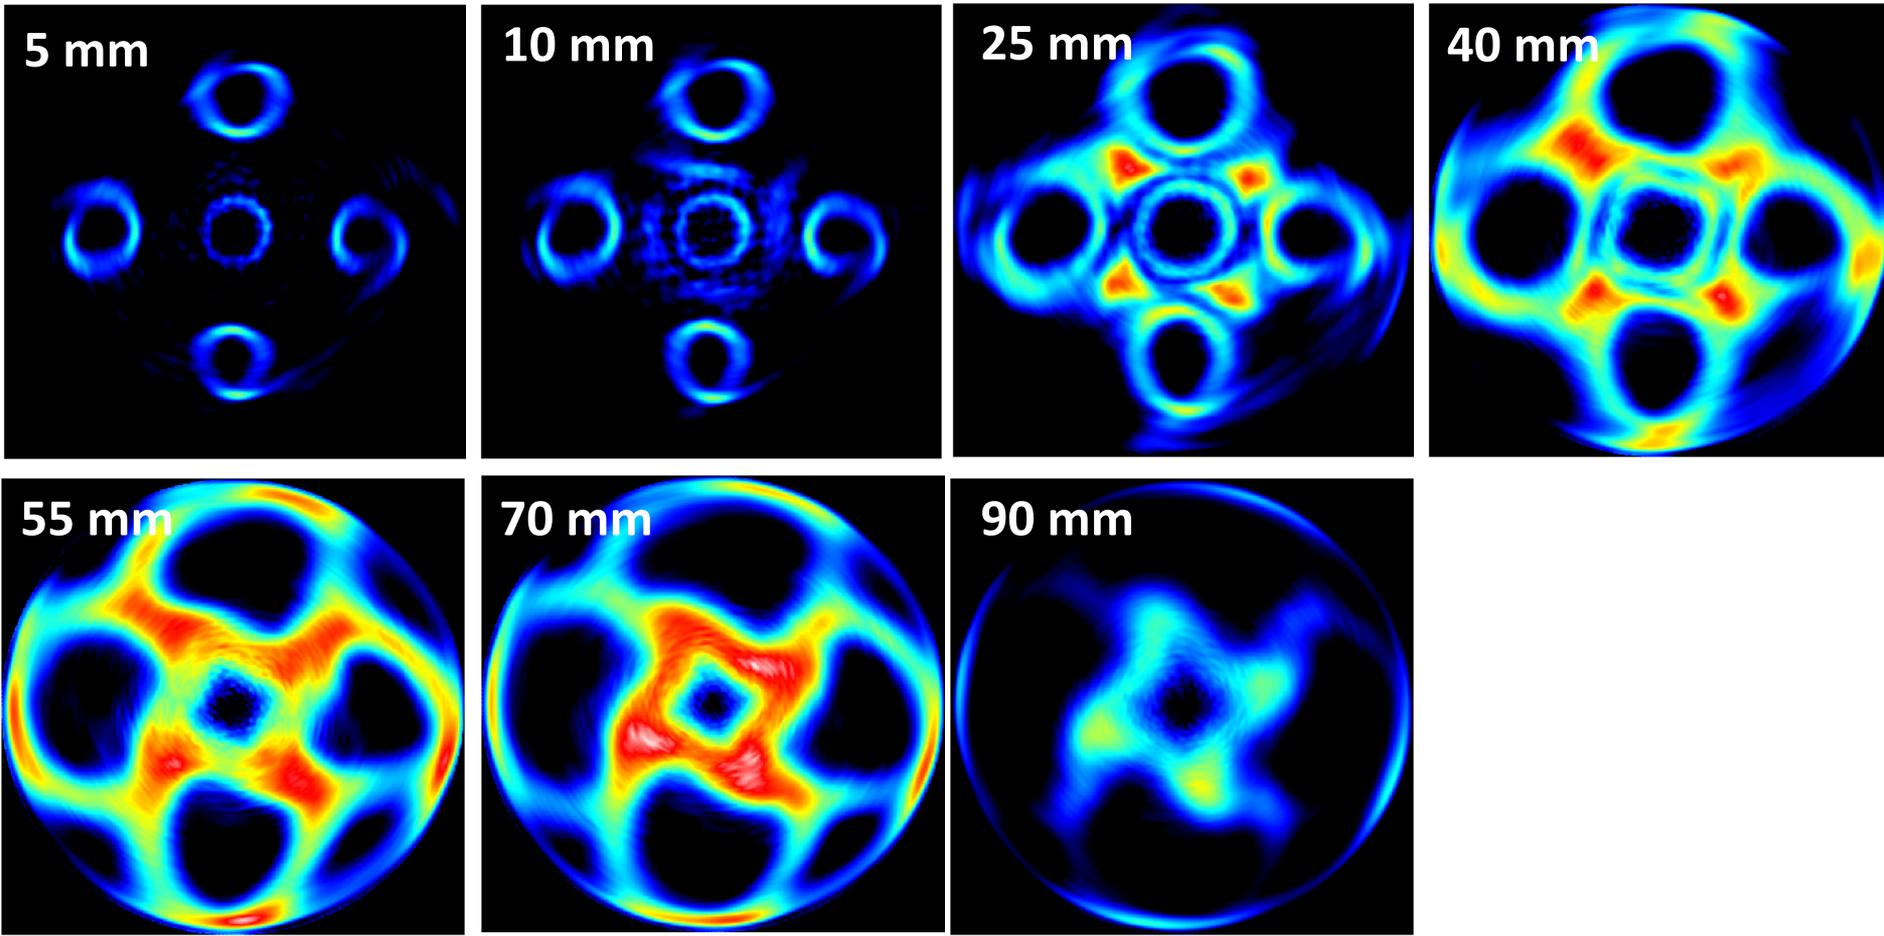

$\phi = 0.60$

Slides through the flame shows center flame lift-off and significant flame-wall interaction at  $\phi = 0.48$

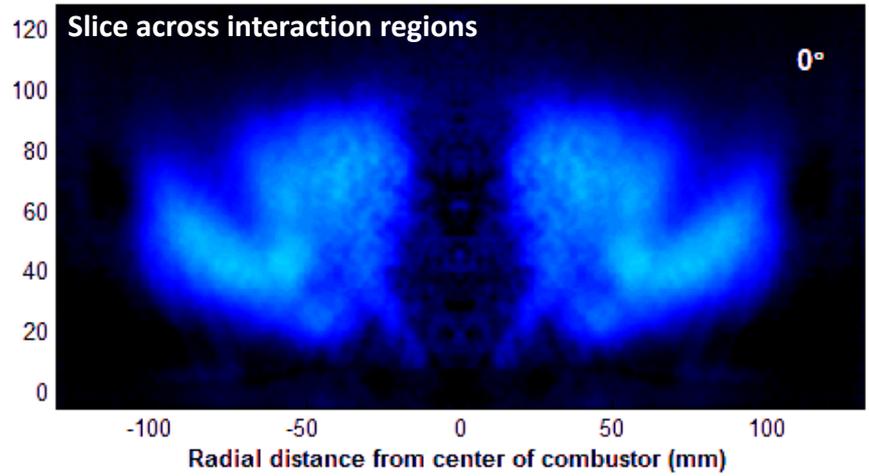

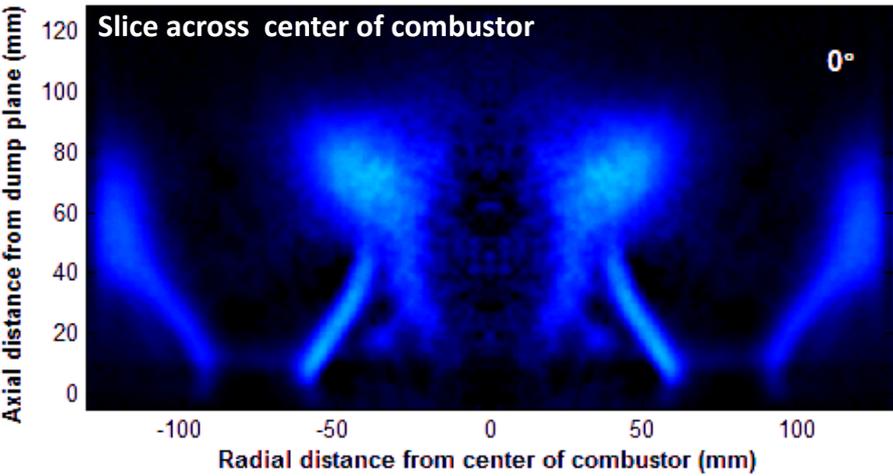

Flame-flame interaction dominates at  $\phi = 0.6$  and center flame, now attached, shows significant non-axisymmetry

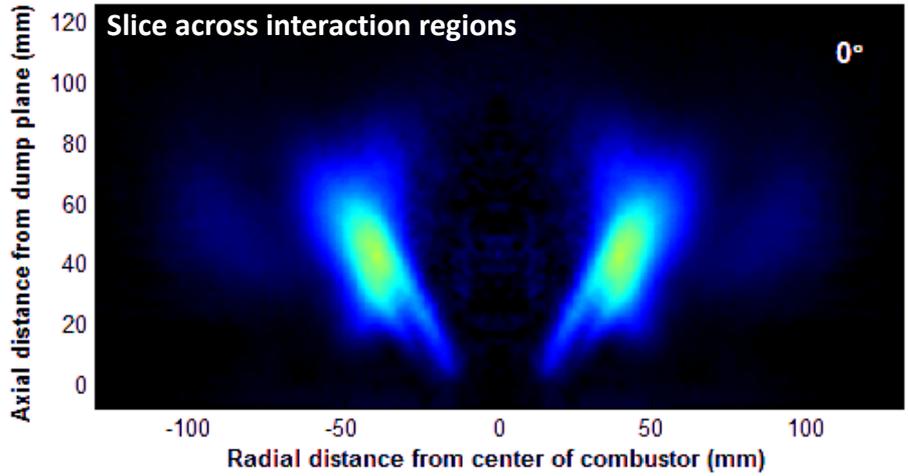

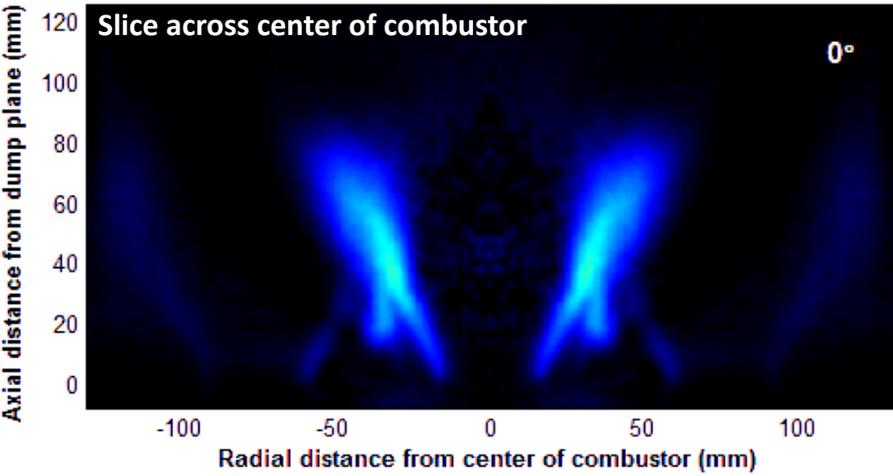

# Data from our multi-nozzle combustor shows that fuel splitting changes flame structure and oscillation during instability

$\phi = 0.6$  in all nozzles

$\phi = 0.5$  in outer nozzles,  $\phi = 0.8$  in middle nozzle

# Overview of presentation

- Technical approach

- Next steps

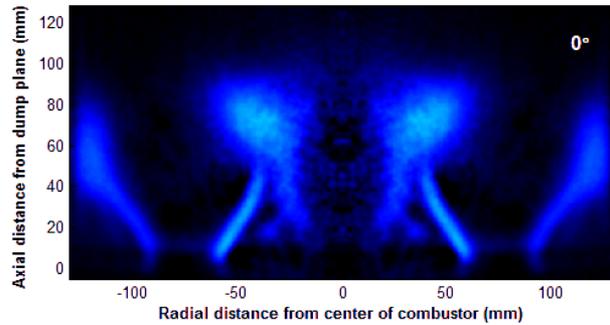

Experimental facilities include both a single-nozzle and multi-nozzle combustor, fuel splitting on multi-nozzle only

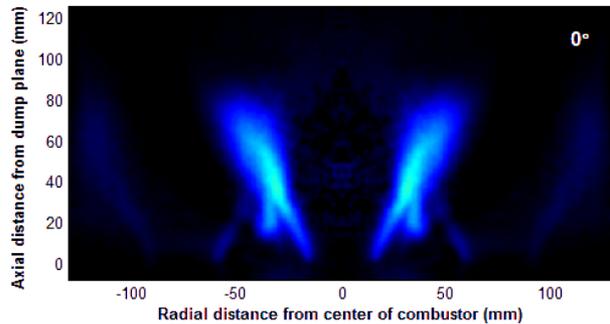

Three types of transients will be considered in the program that mimic the types of transients used in operational turbines

## Fuel Splitting

$\phi = 0.6$  in all nozzles

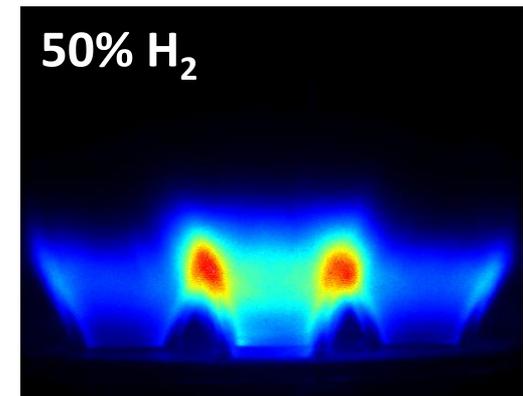

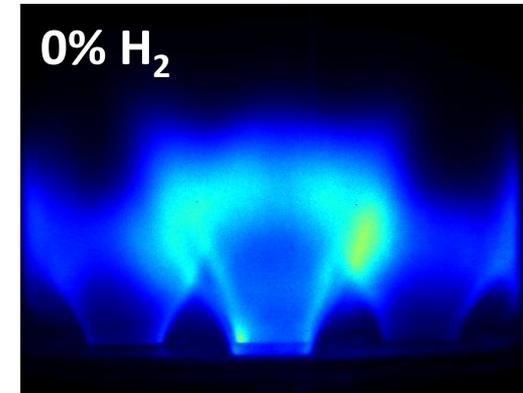

$\phi = 0.5$  in outer nozzles,  
 $\phi = 0.8$  in middle nozzle

## Equivalence Ratio

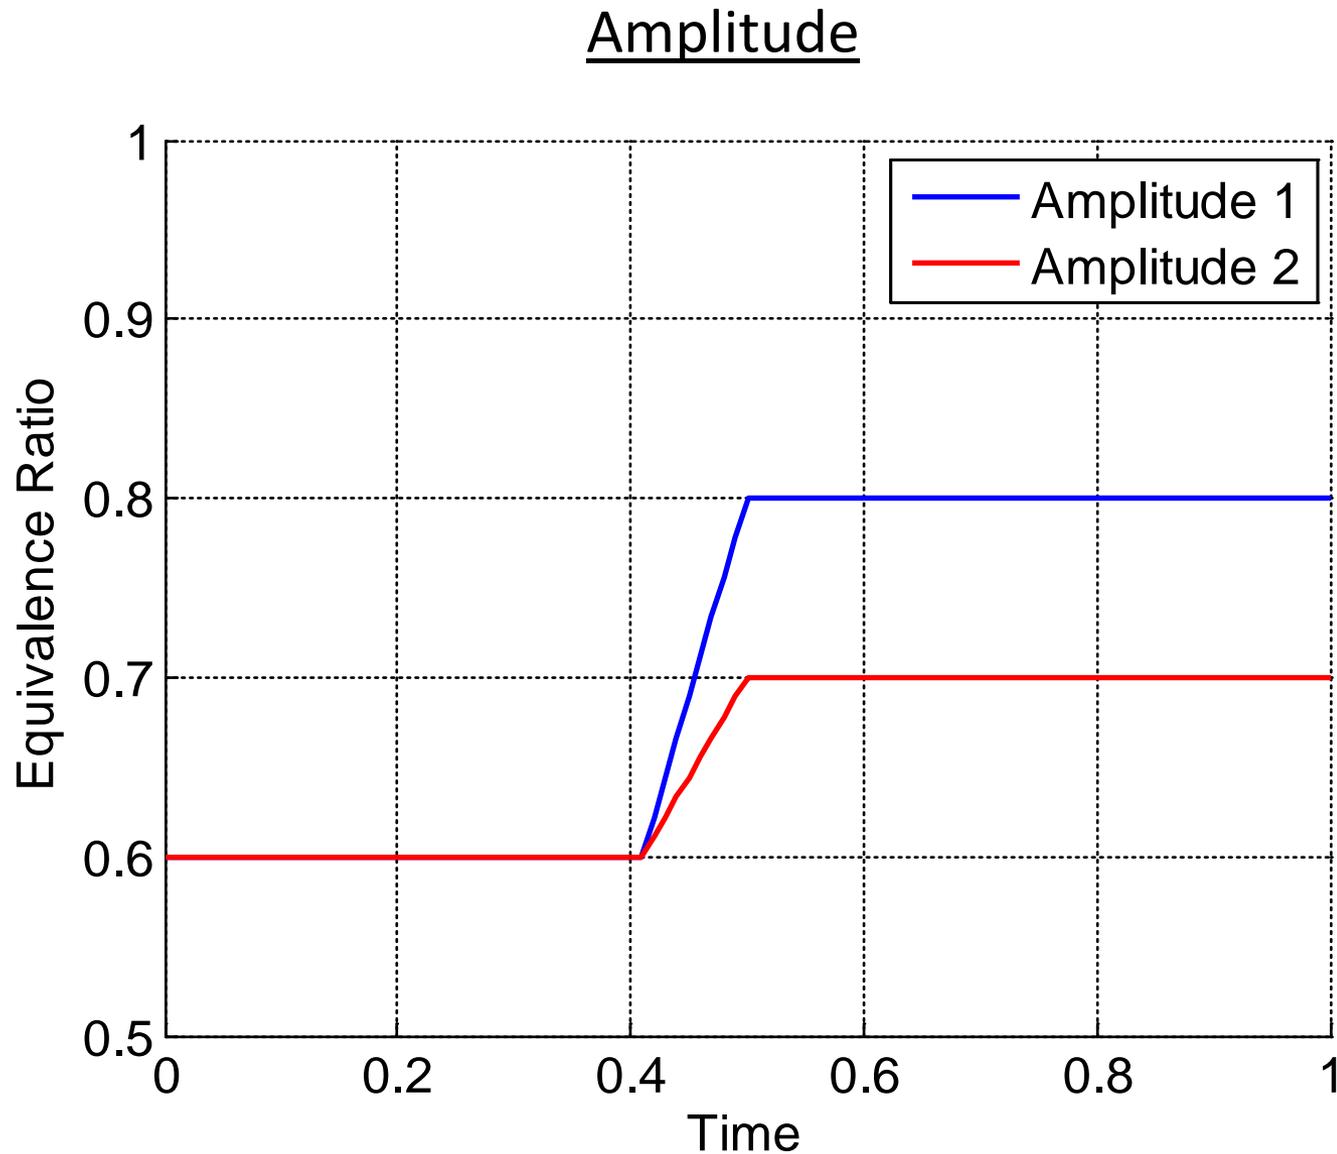

## Fuel Composition

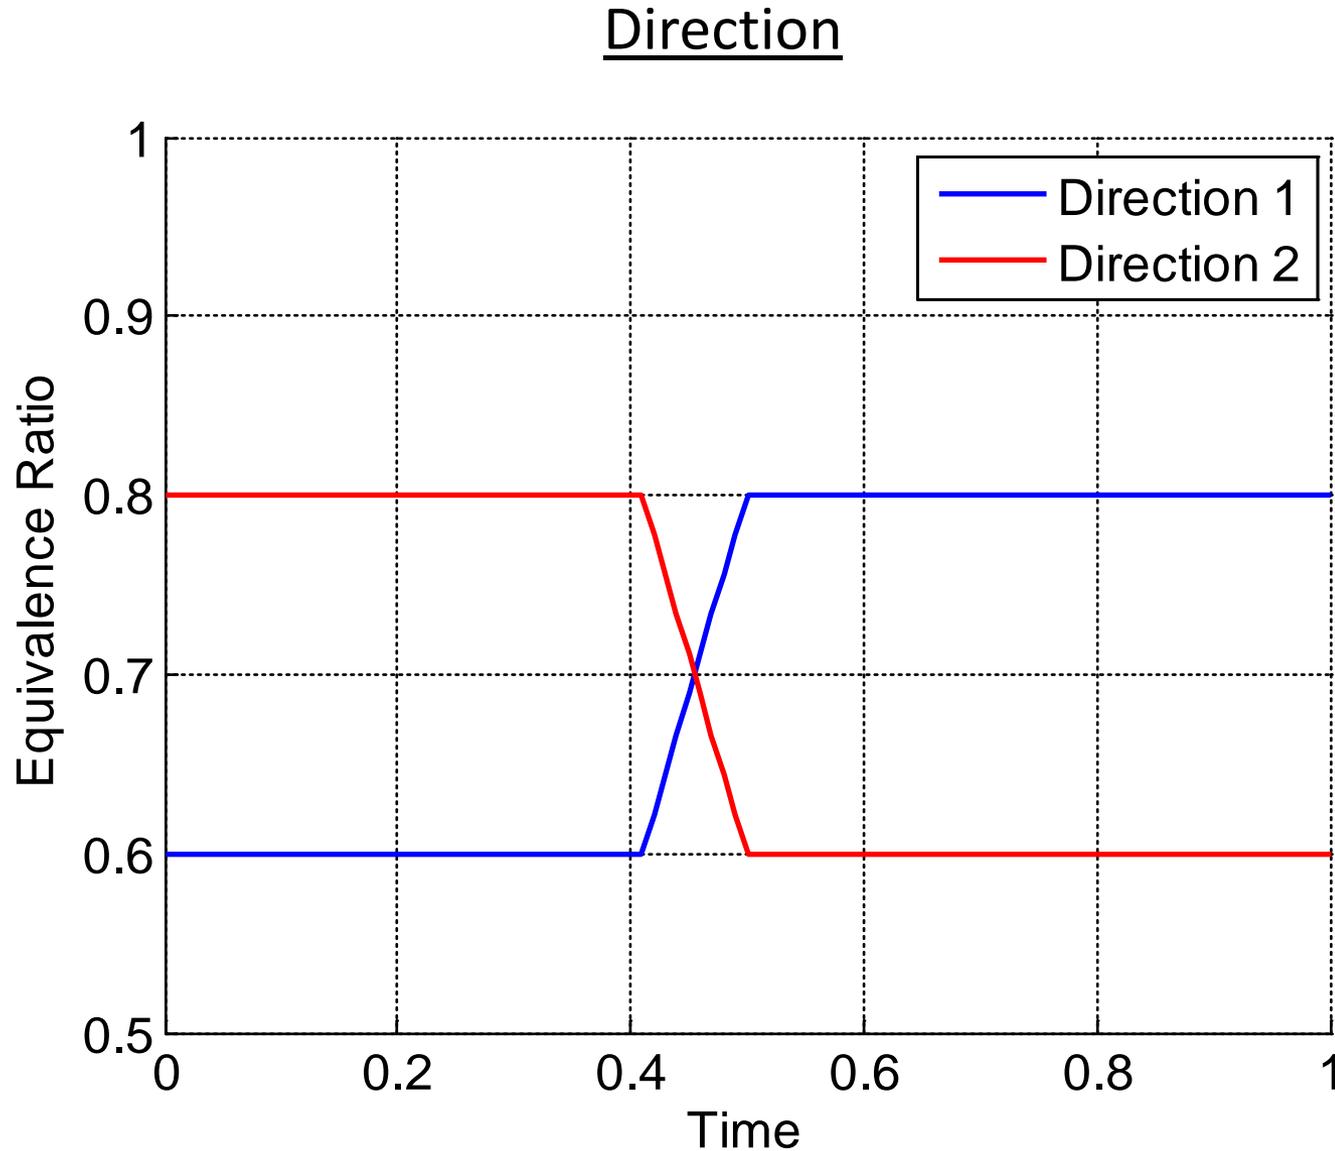

Images obtained from work done by Alex De Rosa (2011)

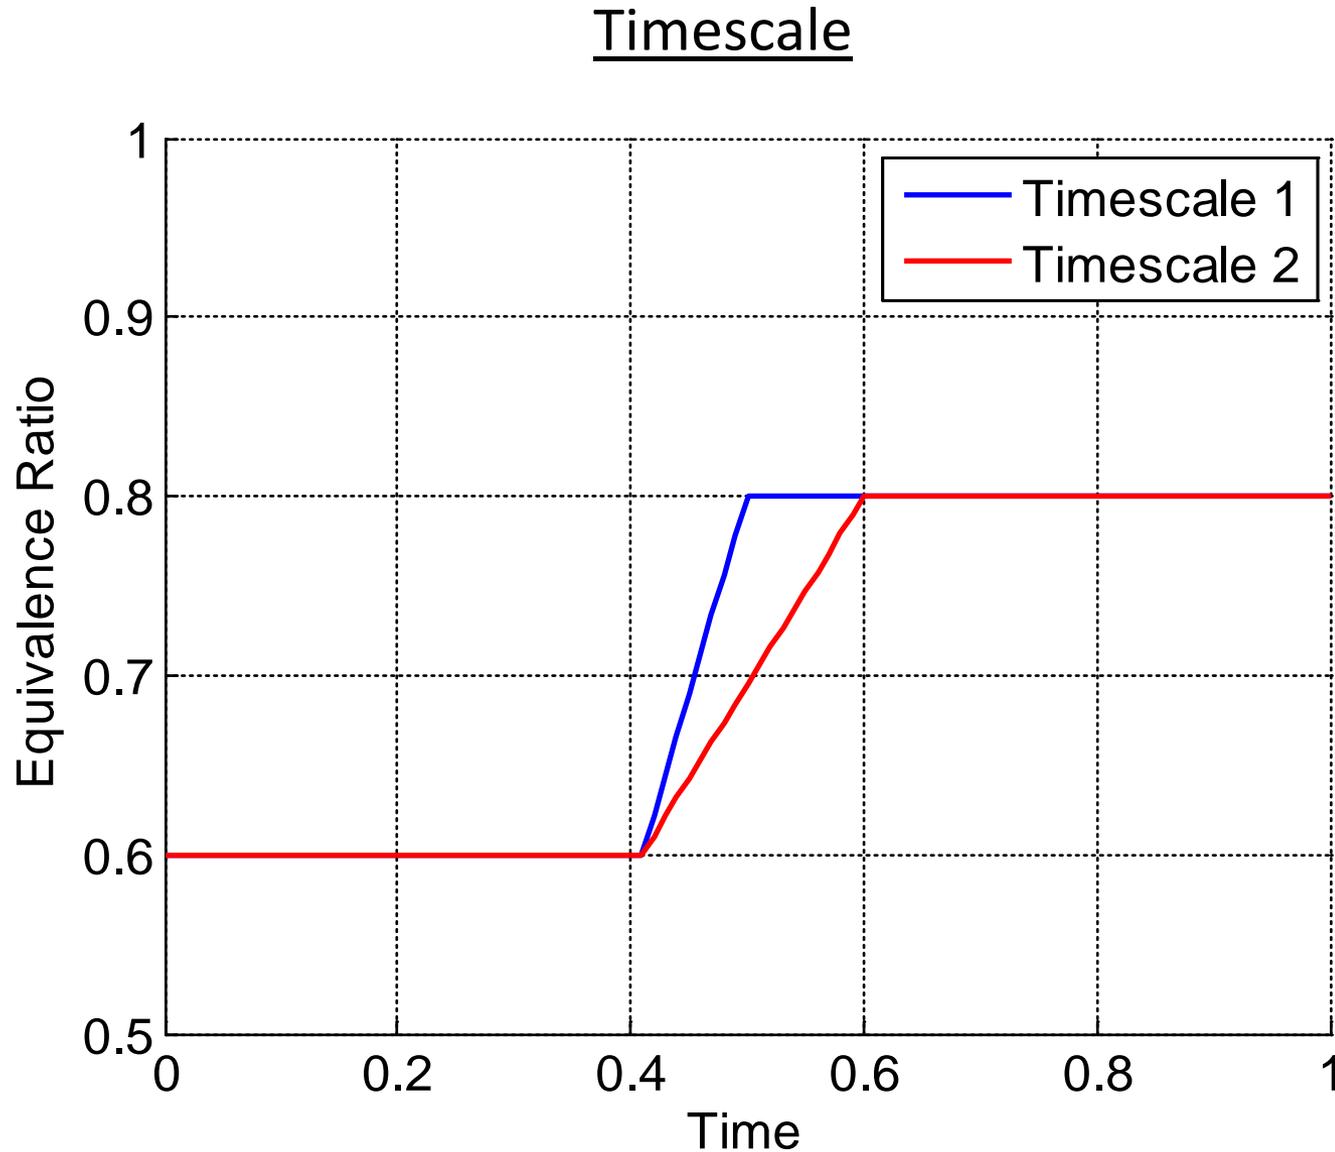

The transients will be quantified using three different metrics:  
*amplitude, timescale, and direction*

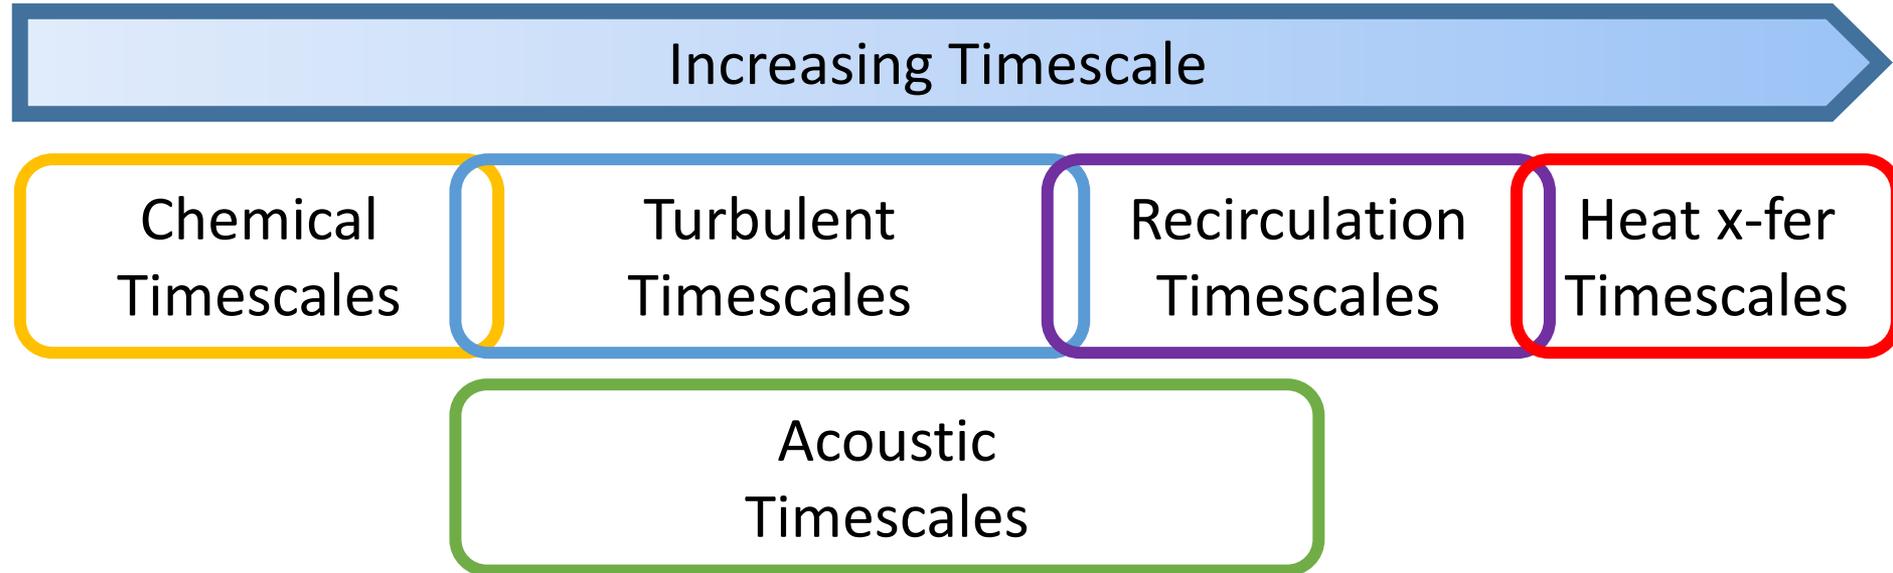

The transients will be quantified using three different metrics:  
*amplitude*, *timescale*, and *direction*

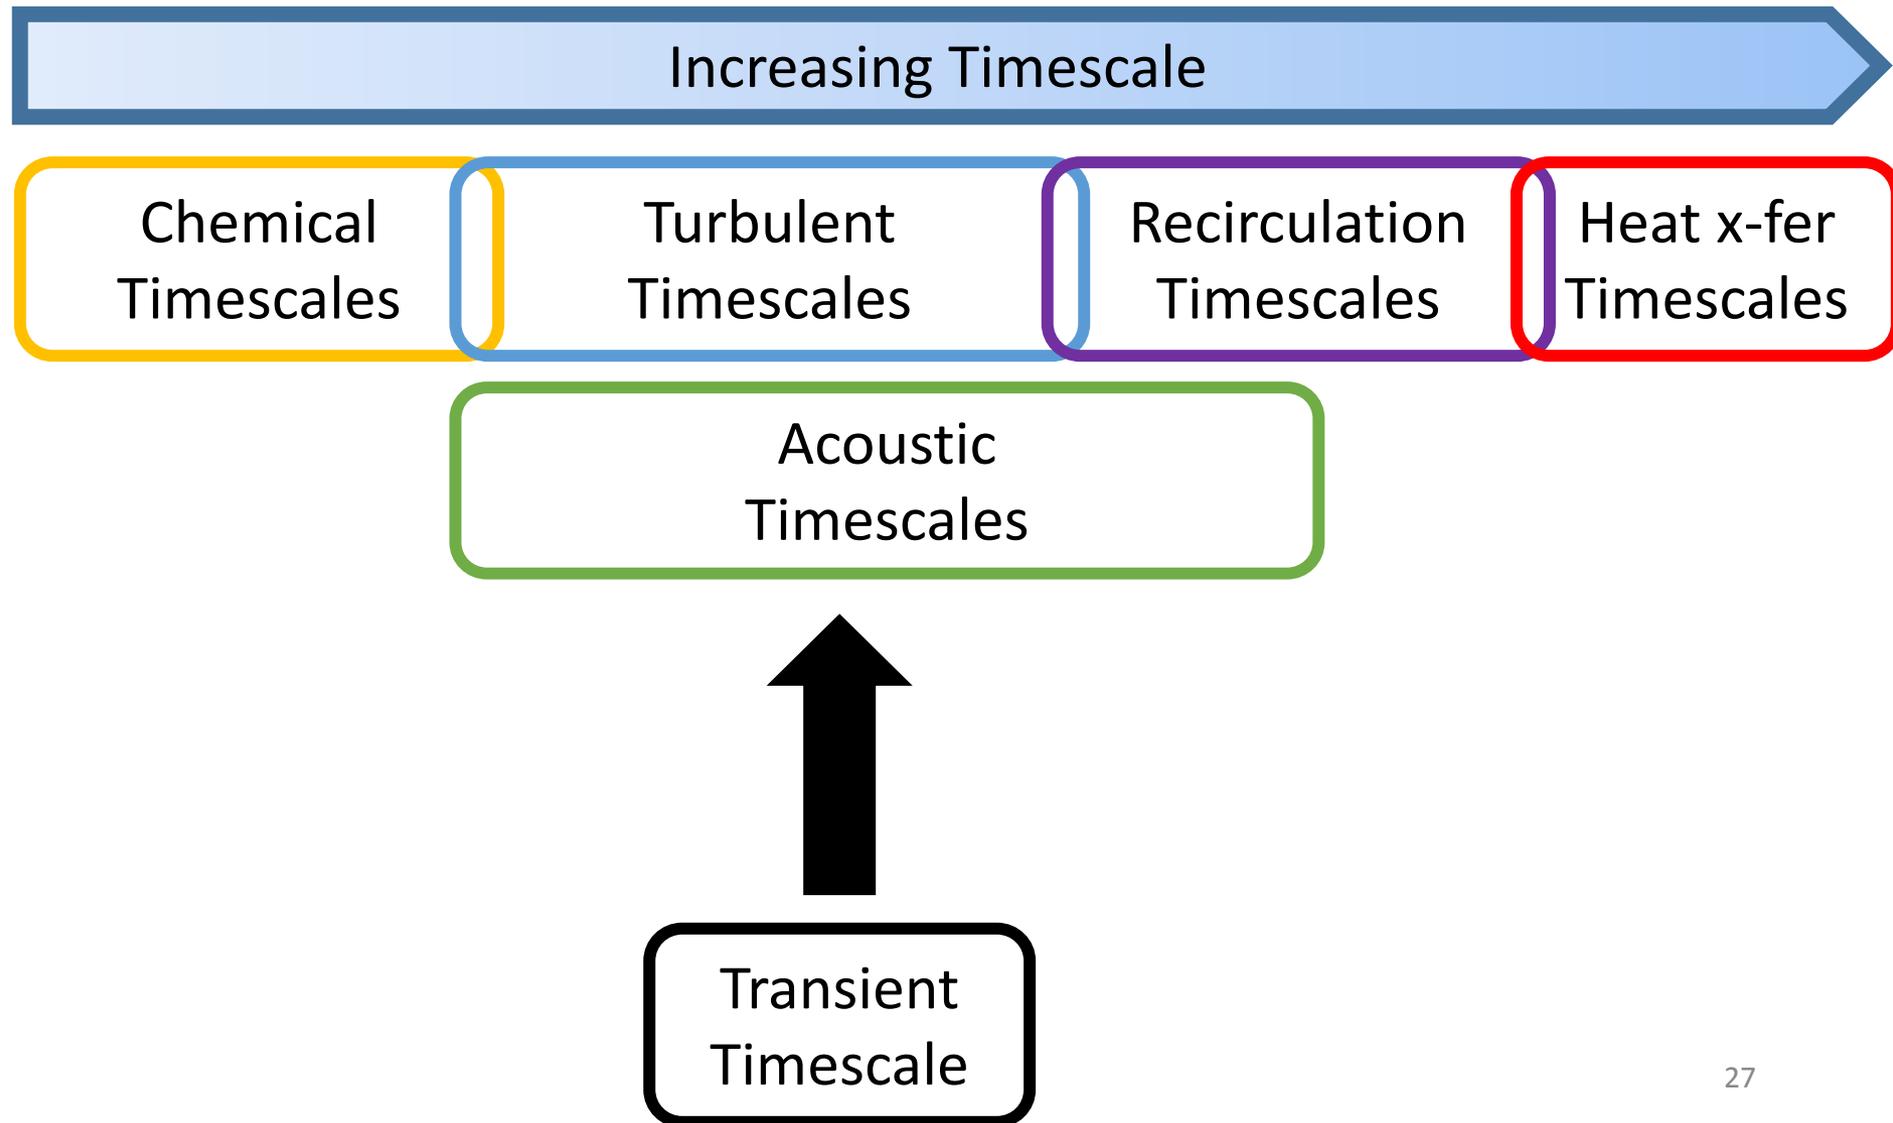

The transients will be quantified using three different metrics:  
*amplitude, timescale, and direction*

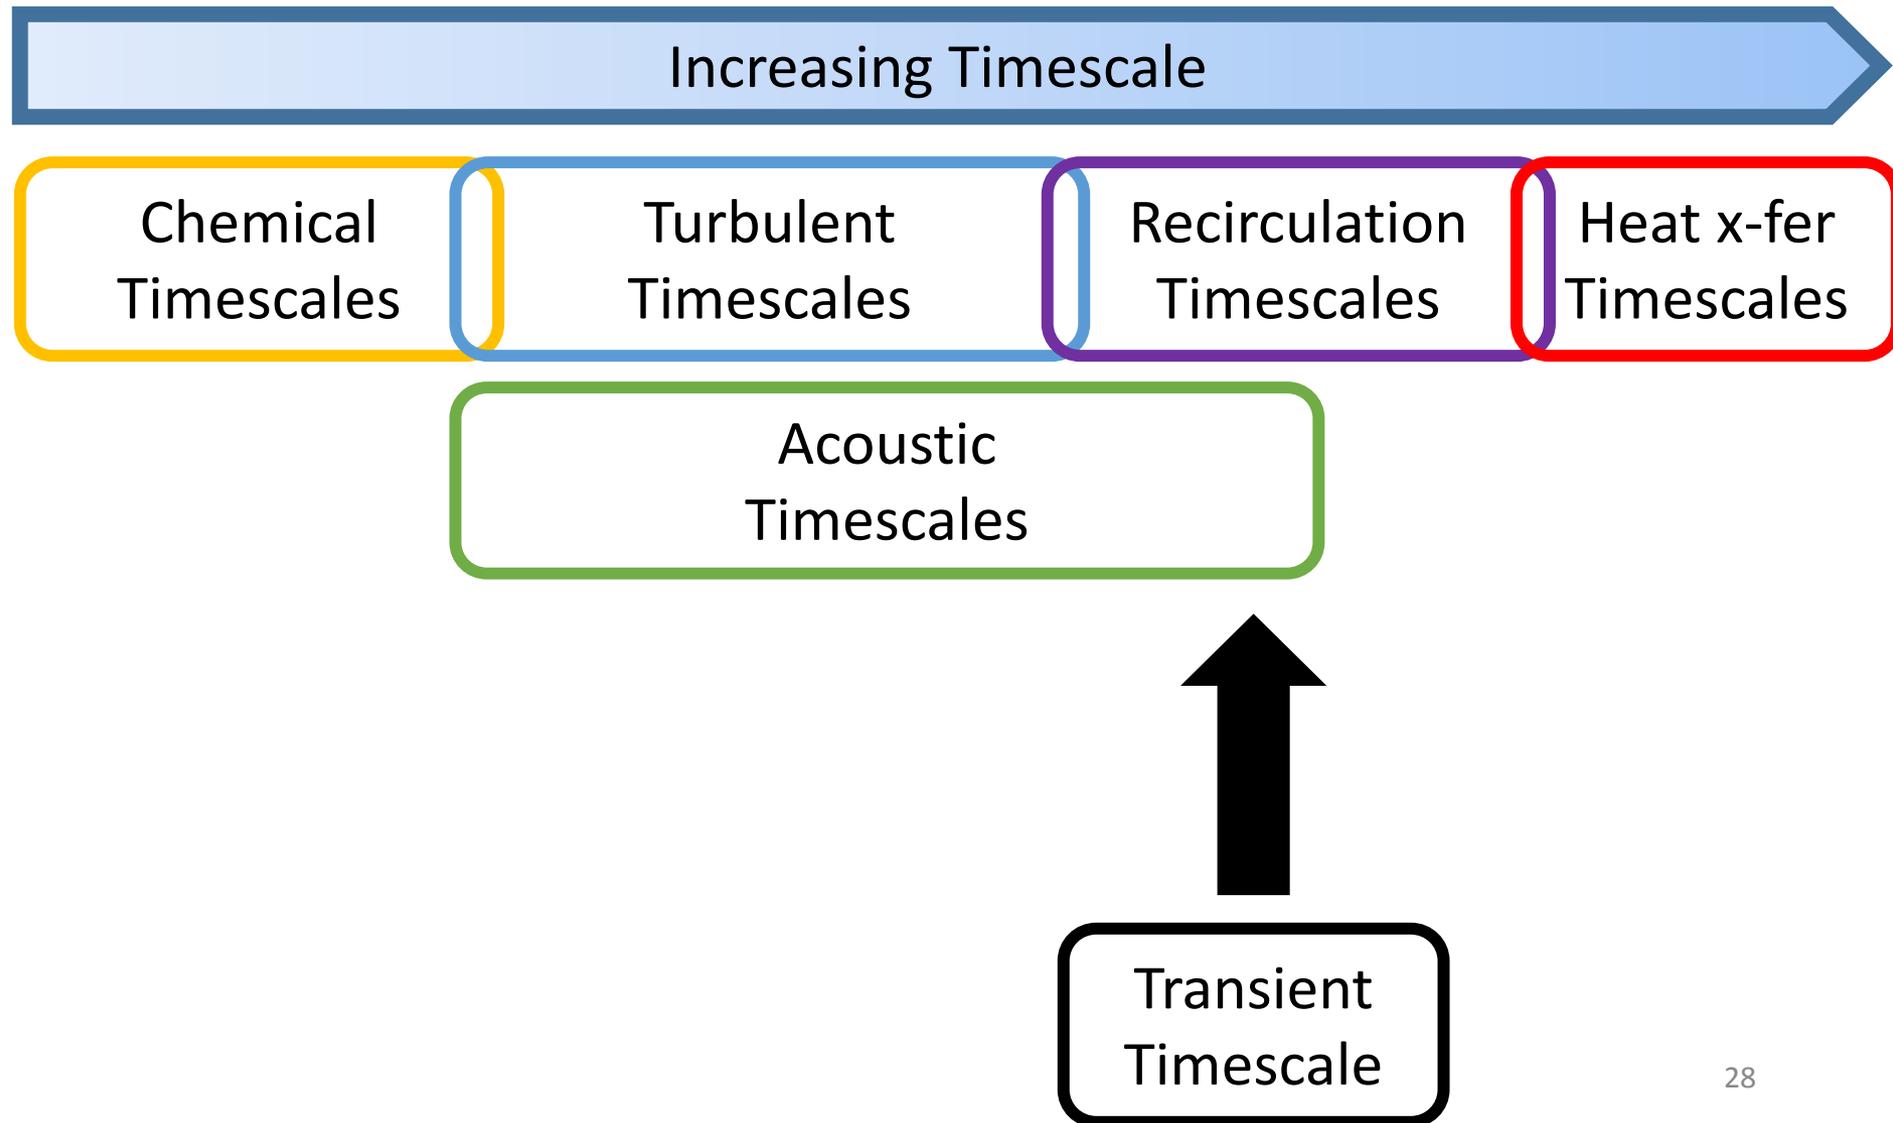

Competition of timescales defines the path of the transient and could impact the final state of the transient event

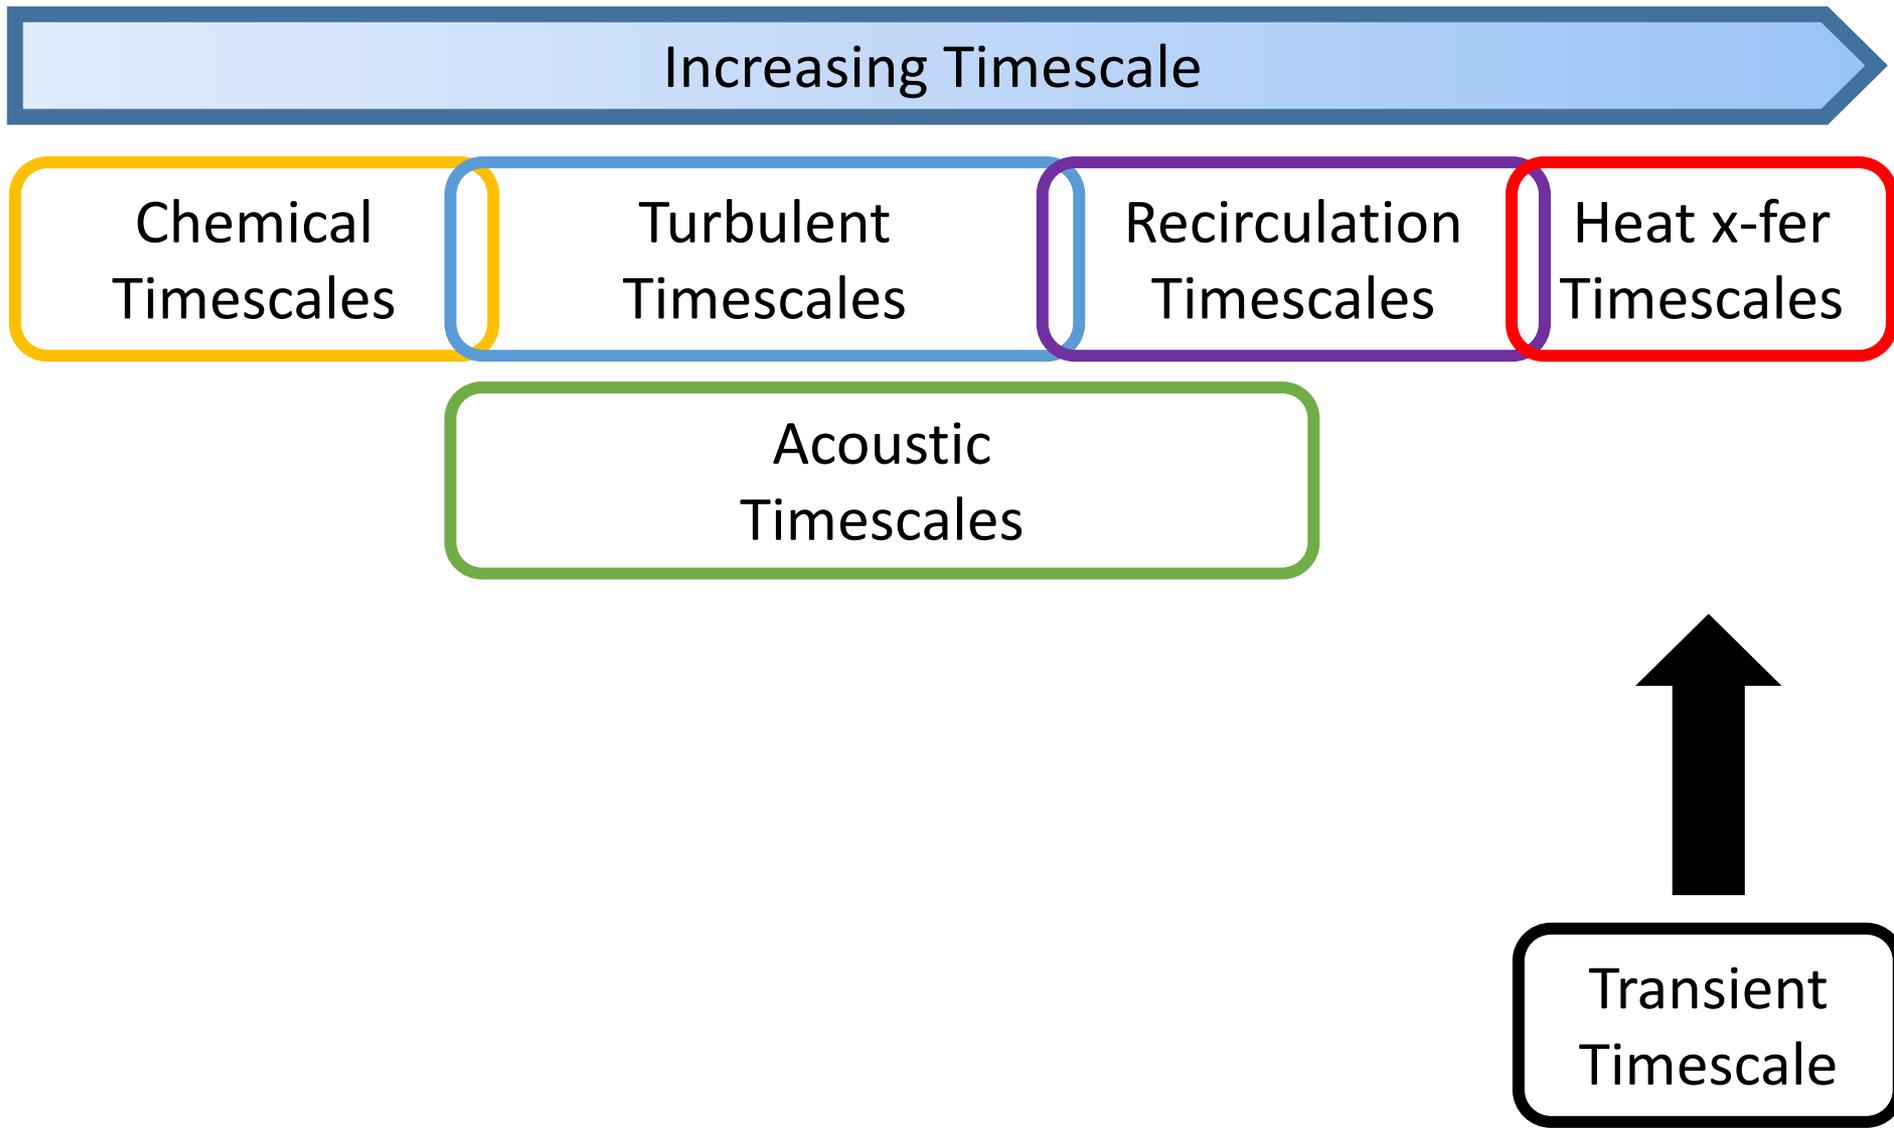

Competition of timescales defines the path of the transient and could impact the final state of the transient event

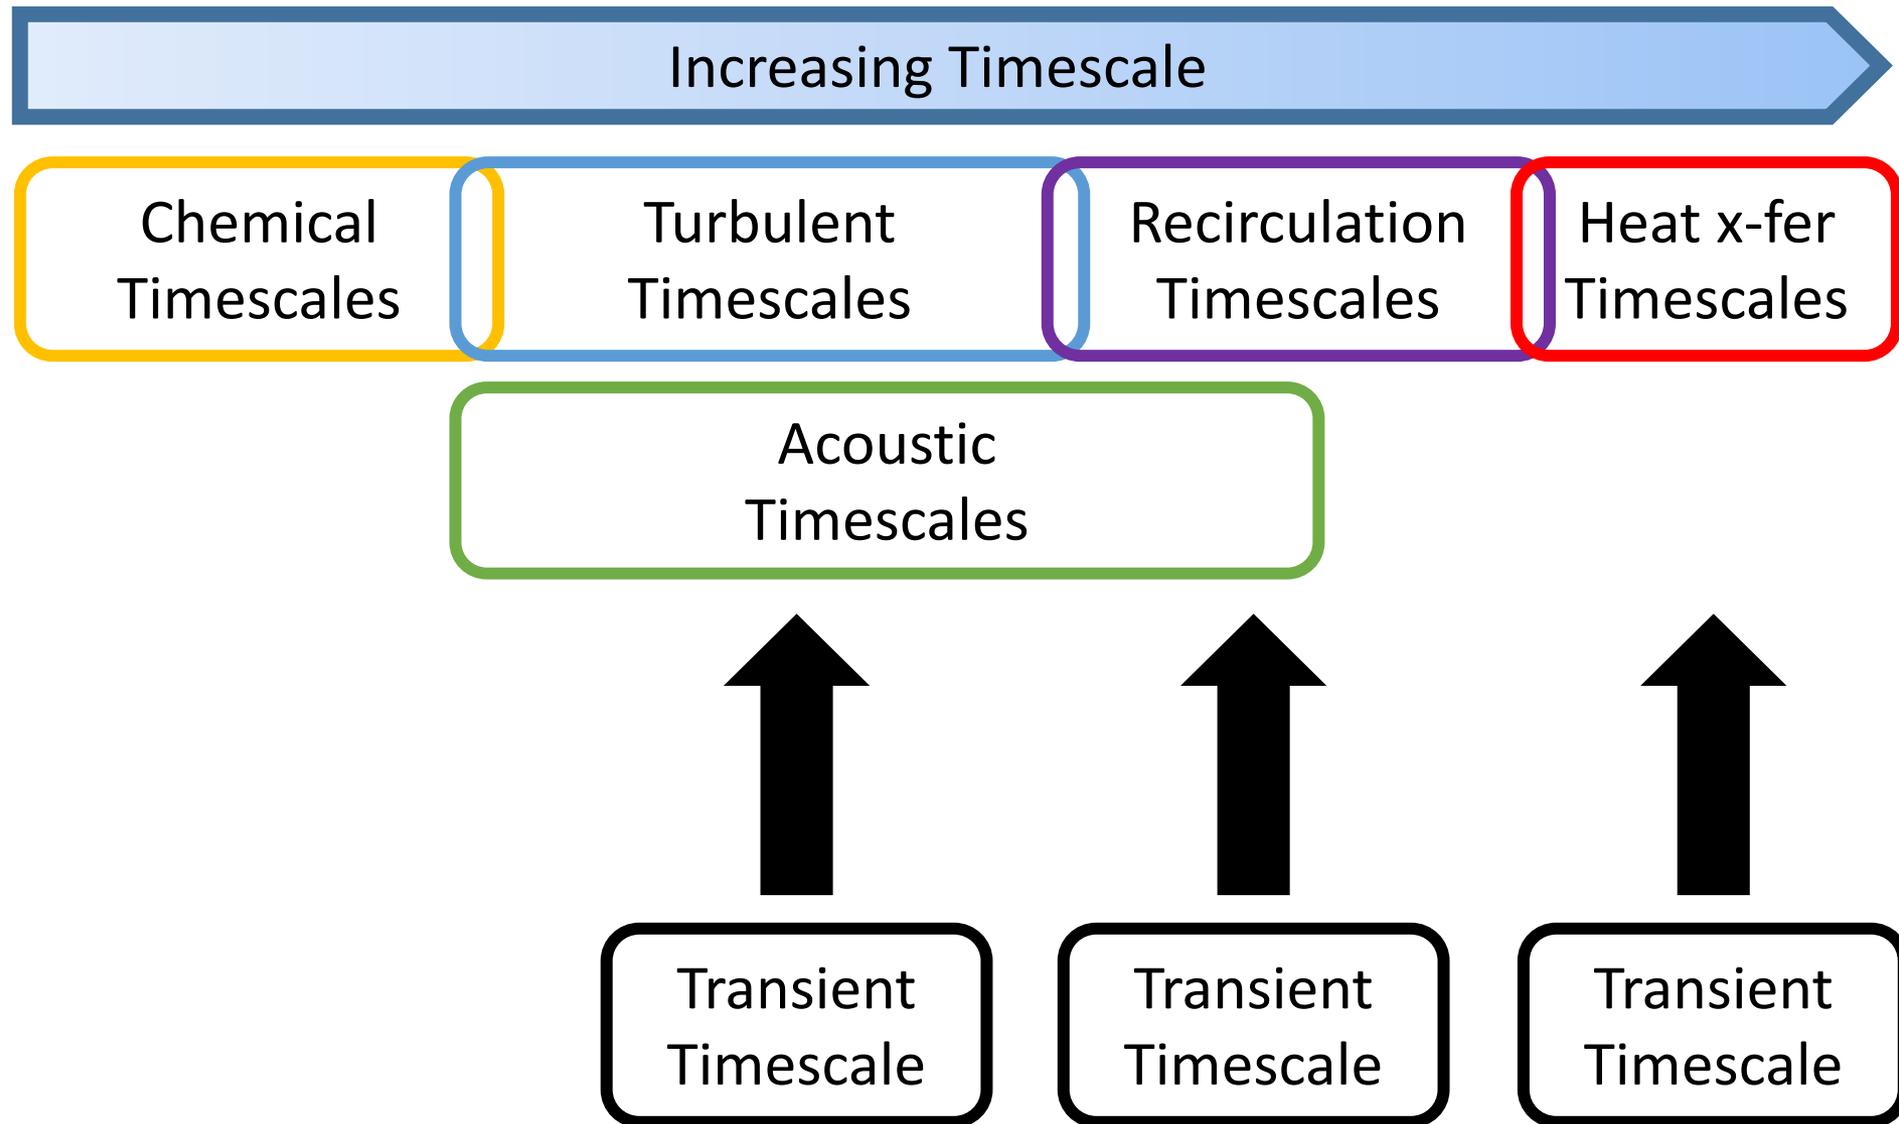

Competition of timescales defines the path of the transient and could impact the final state of the transient event

Competition of timescales defines the path of the transient and could impact the final state of the transient event

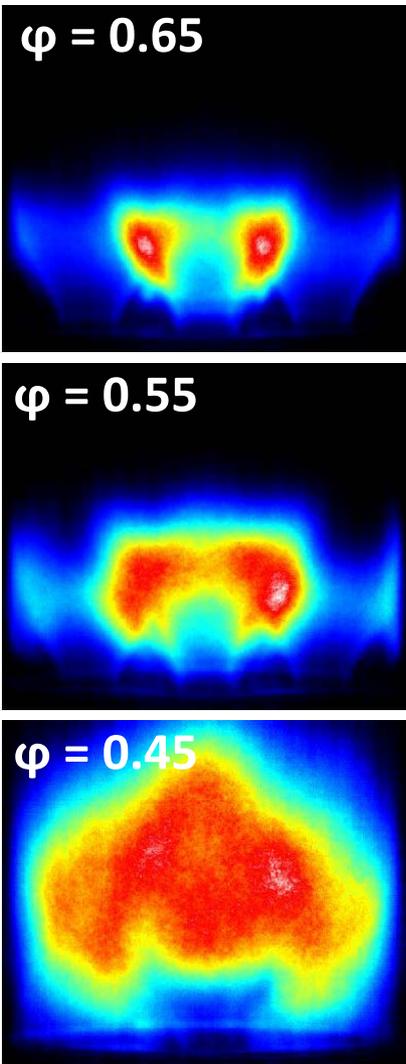

Varying the transient timescales allows for different processes to equilibrate during the transient, changing the path

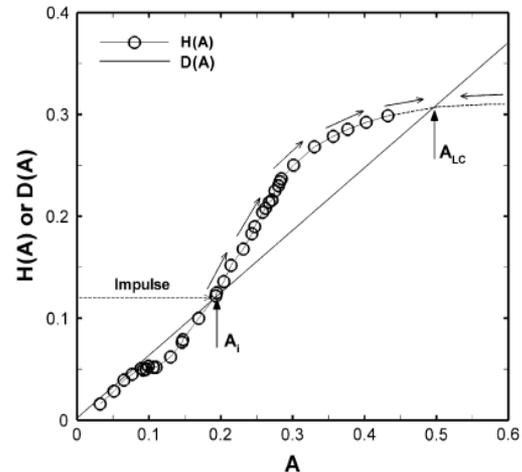

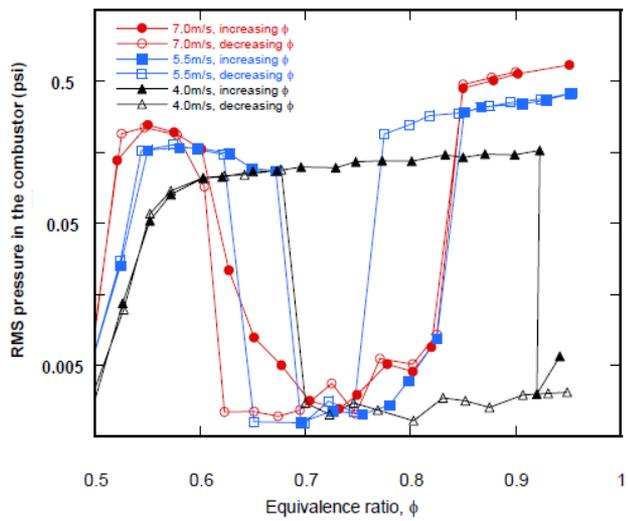

# Project structure includes three stages of experimentation: mapping, transients, and quantification

## Mapping

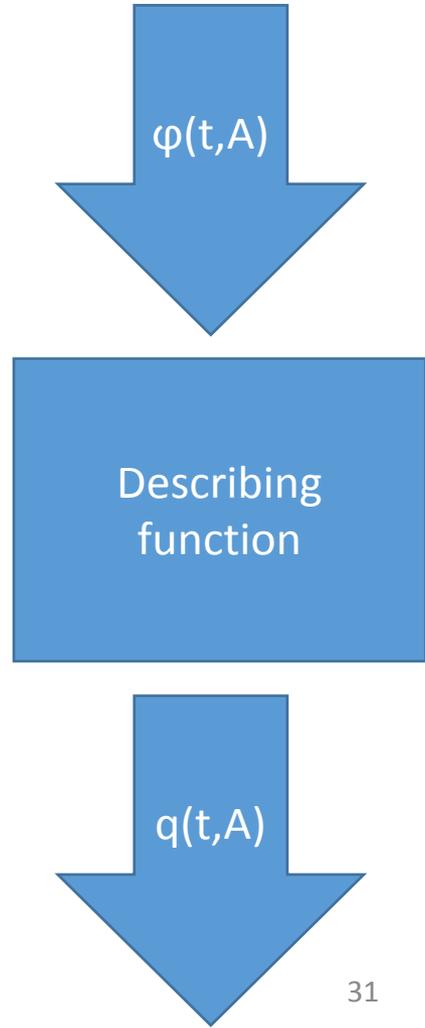

## Transients

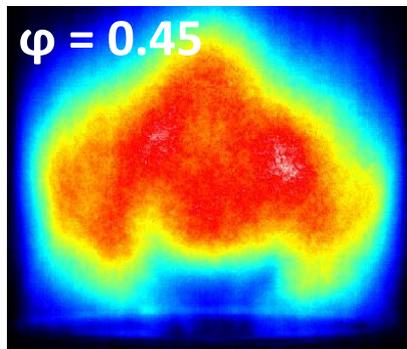

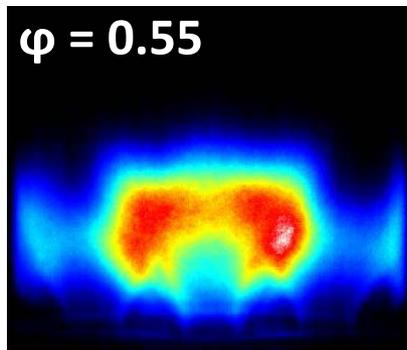

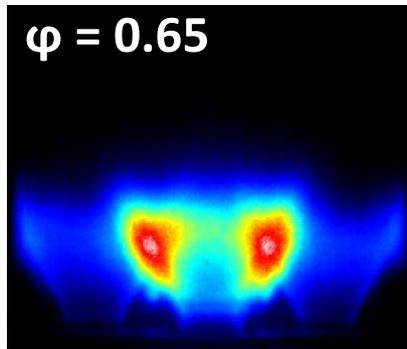

Kim and Hochgreb, 2012

## Quantification

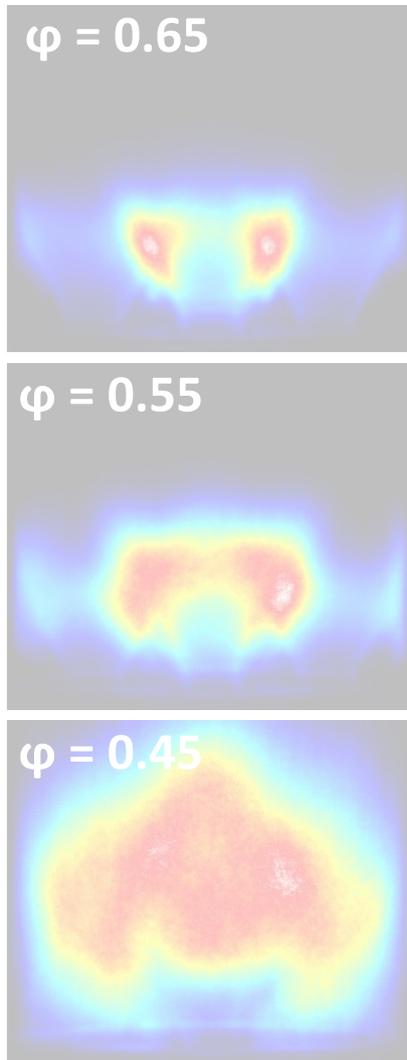

Mapping will include characterization of stability and important combustor timescales

## Mapping

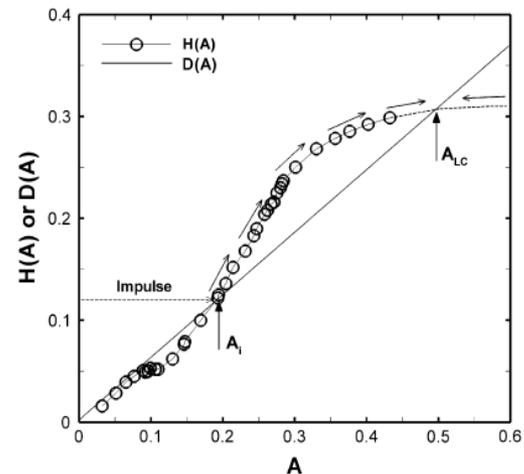

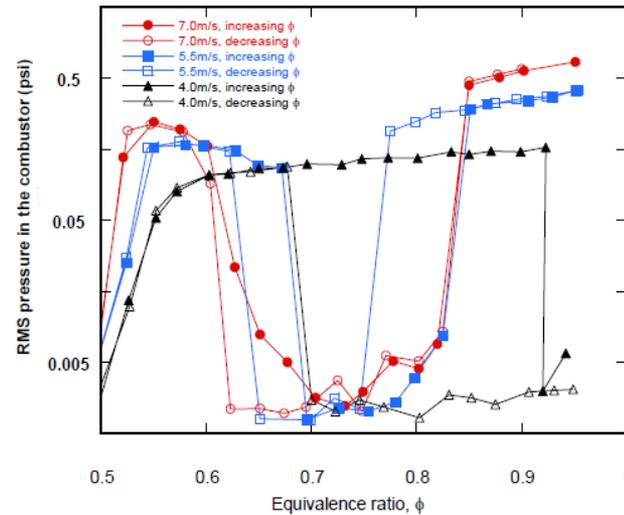

# Transient experiments will be designed based on the mapping, varying the transient *amplitude*, *direction*, and *timescale*

## Mapping

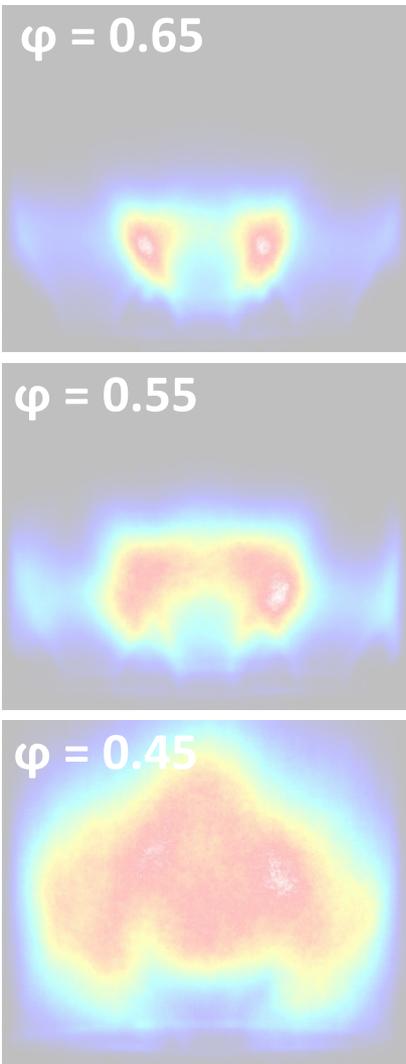

## Transients

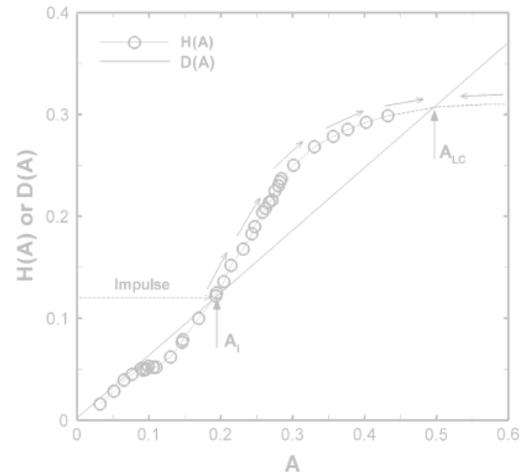

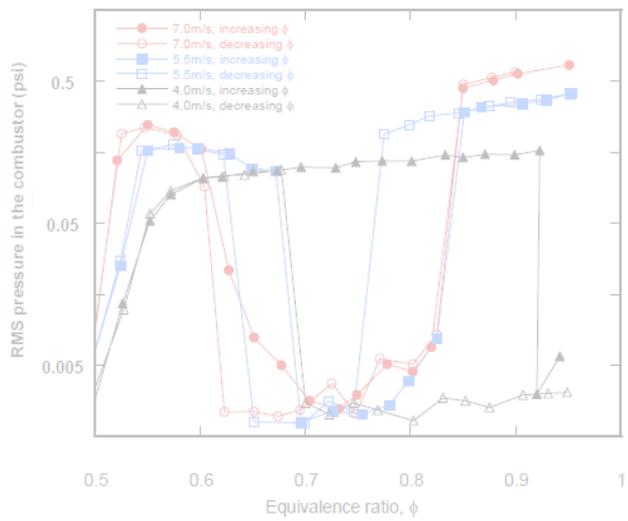

Kim and Hochgreb, 2012

Both the transient input and the combustor response will be quantified and a describing framework will be developed

Mapping

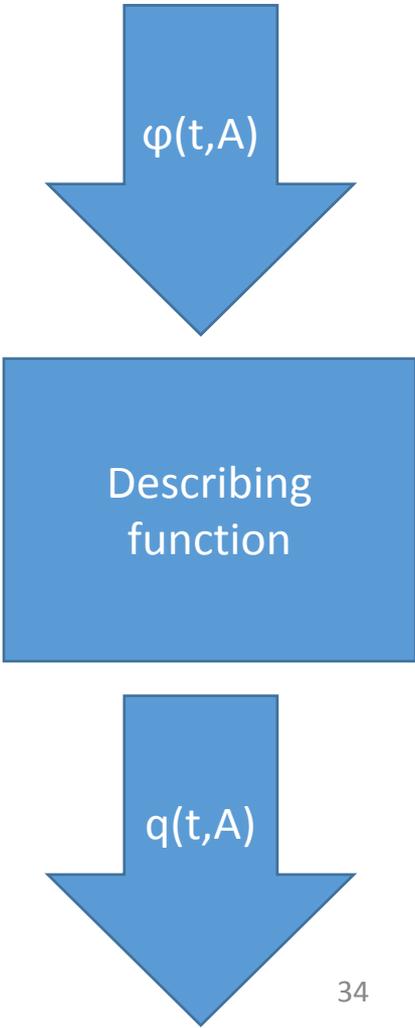

Transients

Kim and Hochgreb, 2012

Quantification

Stability limits of certain operating points are already known, current work focuses on mapping instability with fuel splits

**Inlet temperature = 200°C**

		U (m/s)						
		15	17.5	20	22.5	25	27.5	30
$\phi$	0.40	Yellow	Yellow	Yellow	Yellow	Grey	Grey	Grey
	0.45	Green	Green	Green	Green	Yellow	White	White
	0.50	Yellow	Yellow	Yellow	Yellow	Yellow	Yellow	Yellow
	0.55	Green	Green	Green	Green	Green	Green	Green
	0.60	Green	Green	Green	Green	Green	Red	Red
	0.65	Green	Green	Green	Green	Red	Red	White
	0.70	Green	Green	Green	Red	Red	Green	White

Measurements include:

- Flow rates
- Dynamic pressure
- Surface temperatures
- Time-averaged flame imaging

- Next steps

# Project Management Plan

---

- **Task 1** – Project management and planning
- **Task 2** – Modification of current experimental facility with monitoring diagnostics and new hardware for transient control
- **Task 3** – Map combustor timescales at target operating points
- **Task 4** – Design of transient experiments
- **Task 5** – Fuel split transients
- **Task 6** – Equivalence ratio transients
- **Task 7** – Fuel composition transients
- **Task 8** – Data analysis and determination of prediction/quantification framework

Questions?

# Multi-nozzle steady-state fuel-staging tests

**What is the purpose of these tests? What do we expect to learn?**

- To determine the steady state flame structure at various fuel splits.
- To characterize the different flame structures that exist when fuel splitting is varied, understand the fluid mechanic features that lead to those structures and the nature of the transitions between flame structures.
- To determine the influence of fuel-splitting on self-excited instabilities.

# Questions to answer from the steady-state fuel staging tests

- What causes changes in flame structure with fuel splits? Does fuel splitting change the flow-field, flame phenomena (e.g. flame speed or heat of reaction), or both?
- How can we characterize thermal boundary conditions? What temperatures do we need to monitor?
- Can increasing fuel to the middle nozzle during an unstable test condition make it stable?
- Are there cases where increasing fuel to the middle nozzle during a stable test condition makes it unstable?
- Can fuel staging improve flame stability such that the combustor can be operated closer to the LBO limit than without staging?

# Data from unforced and forced flames are available in a range of operating conditions

# Measurements that will be made in steady state tests

- Flame structure will be characterized using digital photographs and line-of-sight CH\* chemiluminescence images.
- K-type thermocouples will be used to make necessary temperature measurements to determine thermal BCs.
- Static pressure will be measured upstream and downstream of the swirler to obtain the mean velocity in each nozzle.
- PCB pressure transducer mounted on dump plane will measure pressure fluctuation in the combustor.
- Additional measurements? PLIF?

PLIF: May provide useful information about the nature of flame-flame interaction along the center plane

# Fuel injection strategy for staging

Two options for adding additional fuel to middle nozzle:

- (1) Inject fuel at swirler → technically premixed
- (2) Inject fuel at air manifold with a choke → fully premixed

Poravee showed using acetone PLIF, that the fuel and air are well mixed at the nozzle exit of the GE-15 nozzle

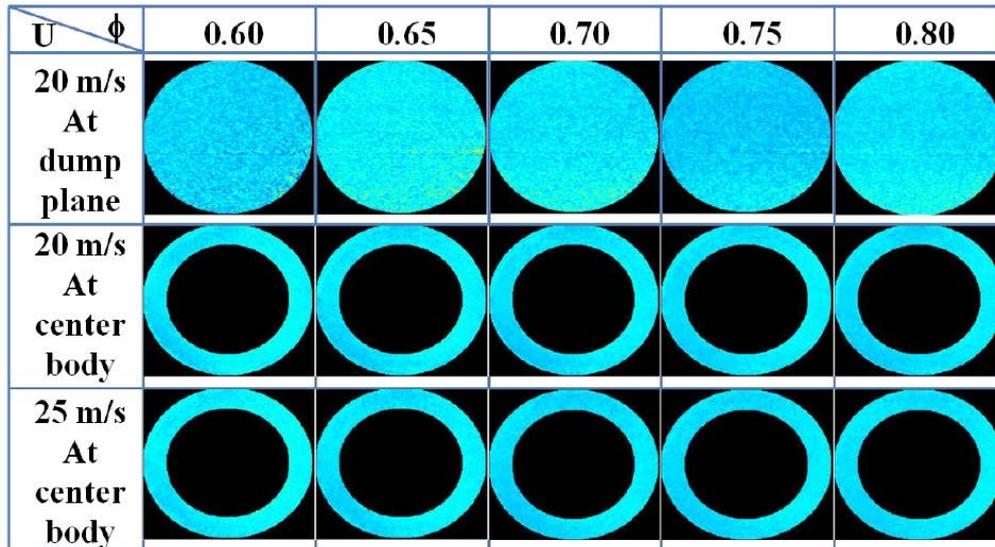

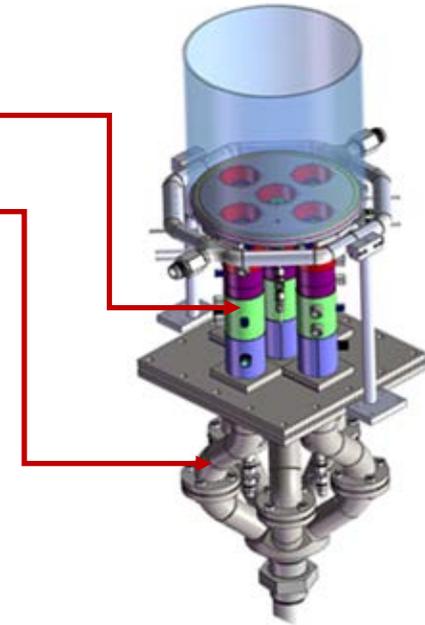

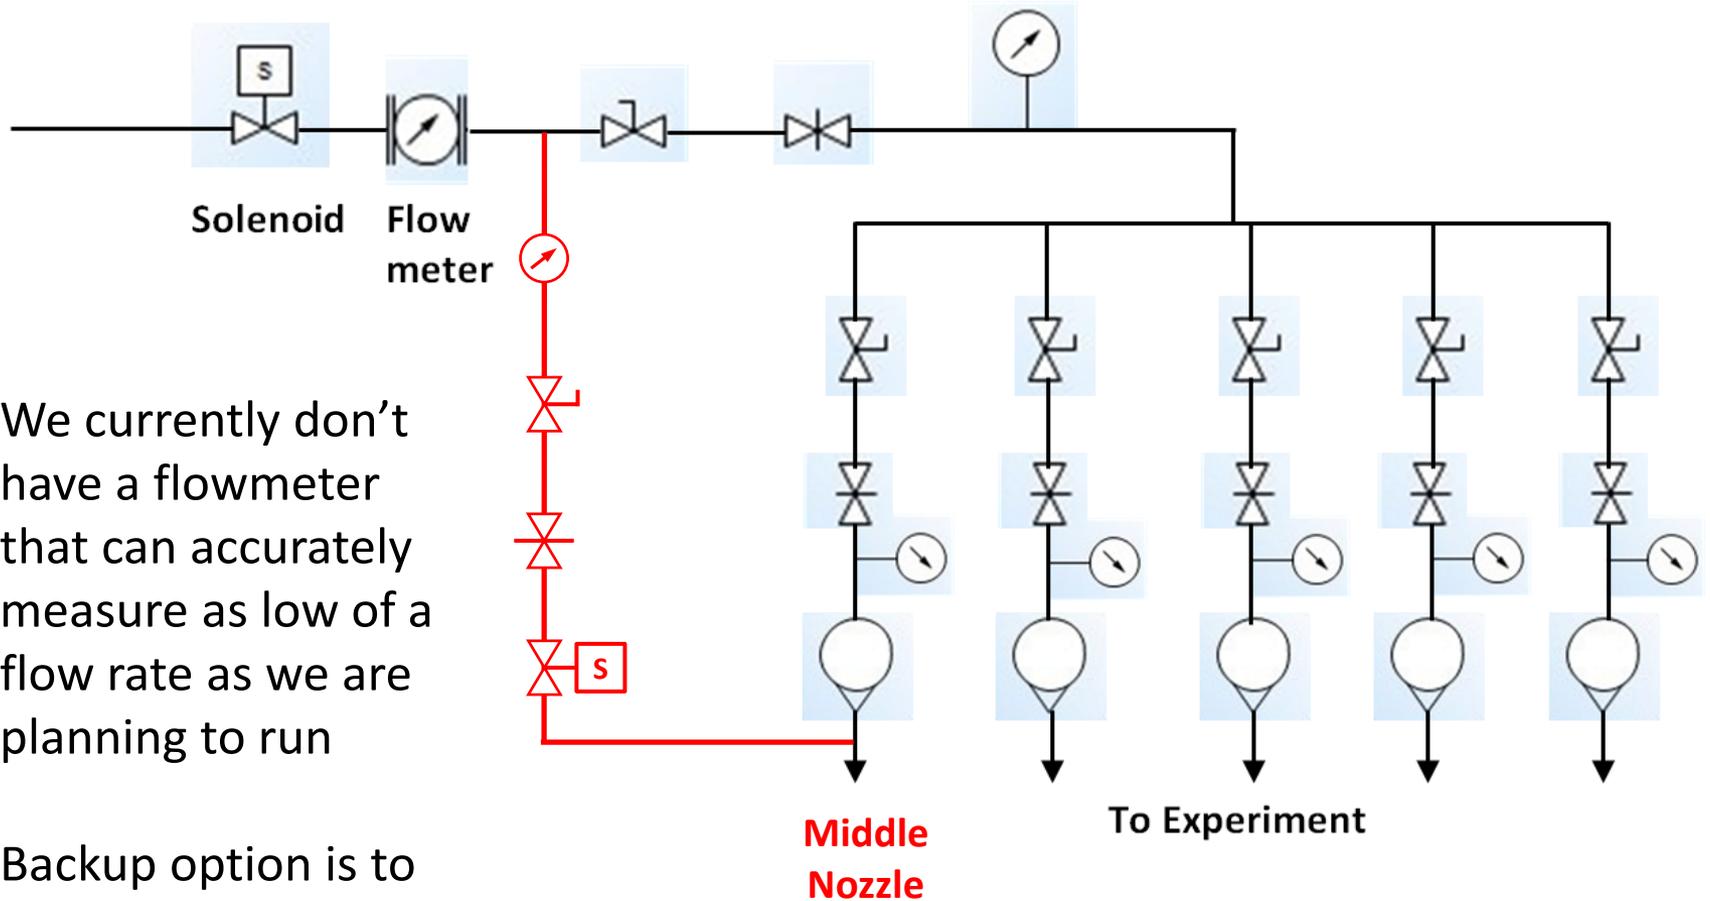

Figure B-4. Spatial distribution of fuel-air mixture results.

The main difference between these then becomes the type of governing mechanisms during the unstable flame case

# Fuel injection strategy for staging

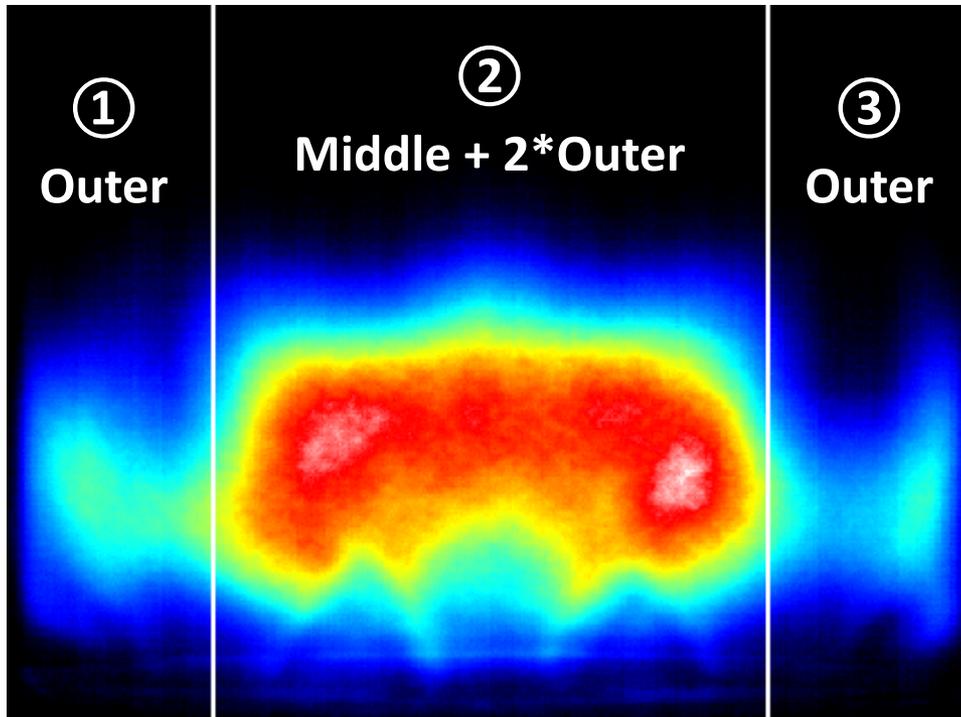

We currently don't have a flowmeter that can accurately measure as low of a flow rate as we are planning to run

Backup option is to use a rotameter

Flame-flame and flame-wall regions are separated from the line-of-sight images to look at relative contribution to  $Q'$

The regions are separated based on the locations of the centers of the outer nozzles

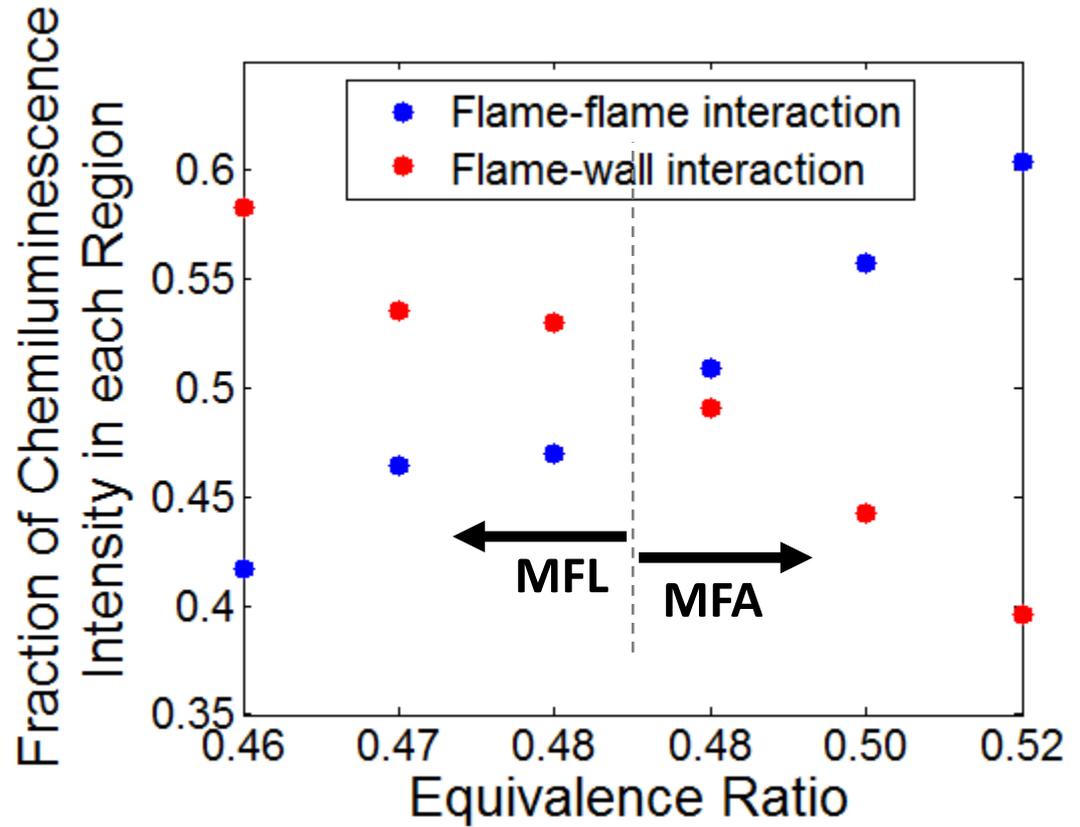

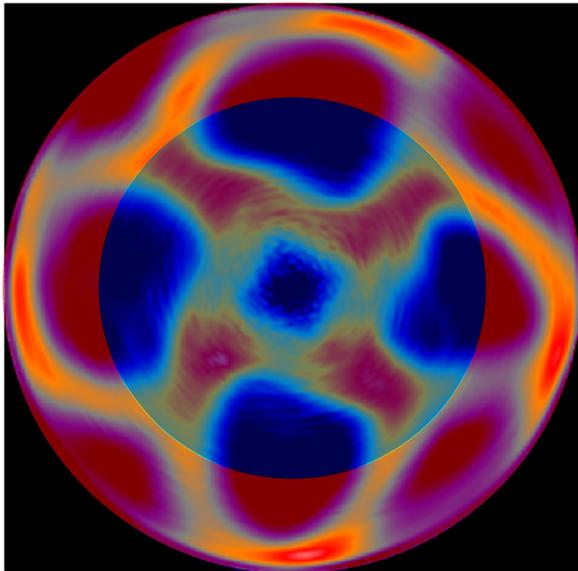

Chemiluminescence emission  
from flame-flame interaction  
region

$$CH^*_{F-F} = \textcircled{2} - [\textcircled{1} + \textcircled{3}]$$

Chemiluminescence emission  
from flame-wall interaction  
region

$$CH^*_{F-W} = CH^*_{Total} - CH^*_{F-F}$$

The majority of heat release rate occurs in the flame-flame interaction region when the middle flame is attached

Very limited data is available on the behavior of flames at different fuel splits except in the cases of flame piloting

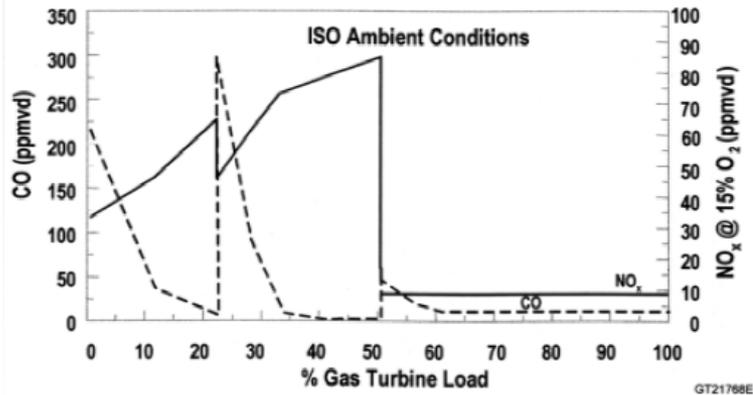

Figure 9. MS7001EA/MS9001E emissions - natural gas fuel

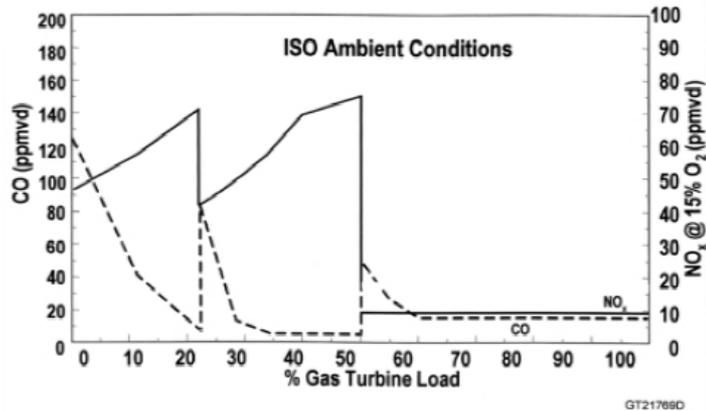

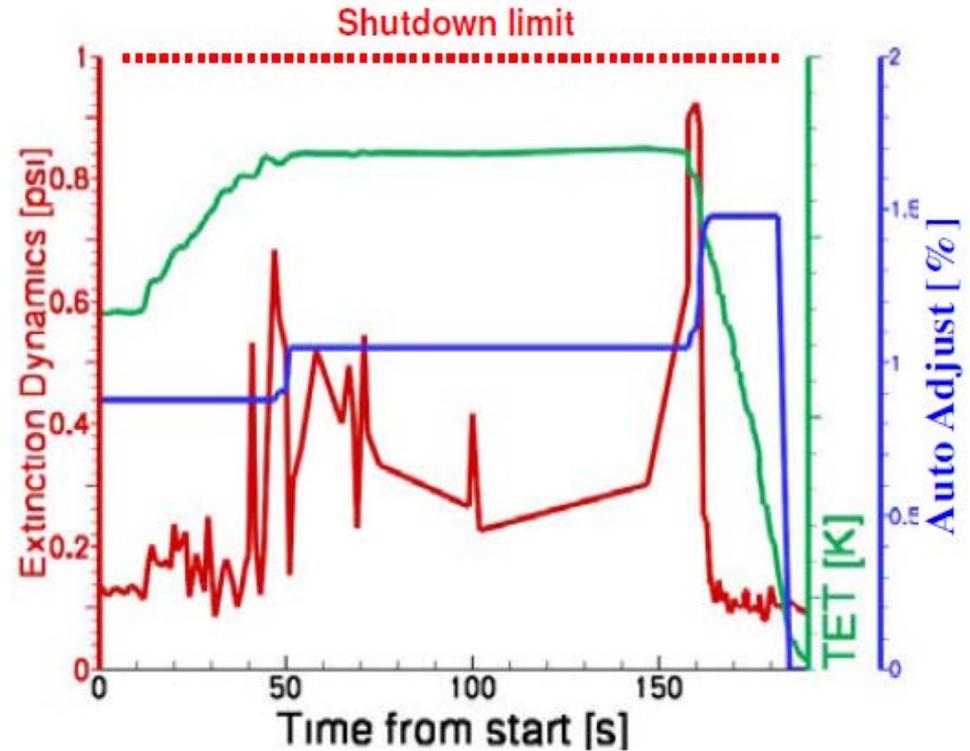

Figure 10. MS6001B emissions - natural gas

Transient operation of a Siemens SGT-200 (Bulat *et al.* 2007)
